ActiveRecord

Active Record is the M in MVC the model - which is the layer of the system responsible for representing business data and logic. Active Record facilitates the creation and use of business objects whose data requires persistent storage to a database. It is an implementation of the Active Record pattern which itself is a description of an Object Relational Mapping system.

ActiveRecord (cont)

In Active Record, objects carry both persistent data and behavior which operates on that data. Active Record takes the opinion that ensuring data access logic as part of the object will educate users of that object on how to write to and read from the database. Active Record gives us several

mechanisms, the most important being the ability to: Represent models and their

Represent associations between these models.

data.

Represent inheritance hierarchies through related models. Validate models before they get persisted to the database. Perform database operations in an object-oriented fashion.

Object Relational Mapping

Object Relational Mapping, commonly referred to as its abbreviation ORM, is a technique that connects the rich objects of an application to tables in a relational database management system. Using ORM, the properties and relationships of the objects in an application can be easily stored and retrieved from a database without writing SQL statements directly and with less overall database access code.

retrieving data from the model, transforming it as appropriate for the view, and then passing it to the view for rendering

Refactor of models

If some code does work from the point of view of an ActiveRecord model, it can go into the model. If some code does work that spans multiple tables/objects, and doesn't really have a clear owner, it could go into a Service Object.

Anything that's attribute-like (like attributes calculated from associations or other attributes) should go into your Active-Record model. If you have logic that has to

orchestrate the saving or updating of multiple models at once, it should go into an Active-Model Form Object.

If code is mostly meant for displaying or formatting models in a view, it should go into a Rails helper or a Presenter.

E-tags

Definition: An E-tag is a response header used to identify a specific version of a resource on a server. It's often a unique identifier, such as a hash or a version number, that changes whenever the resource changes.

E-tags (cont)

Caching: E-tags are crucial for caching mechanisms. When a client requests a resource, it receives an E-tag with the response. On subsequent requests, the client can send this E-tag back to the server with an "If-None-Match" header, allowing the server to determine if the resource has changed. If it hasn't, the server can respond with a "304 Not Modified" status, reducing bandwidth usage by skipping the resource transfer. Content Validation: E-tags also help ensure content integrity. By comparing E-tags, clients and servers can verify that they are accessing the correct version of a resource, ensuring consistency between versions. Implementation: In practice, Etags are generated and managed by the server. Developers might create custom logic to generate these tags or rely on server frameworks that handle them automatically.

E-tags (cont)

E-tags are particularly useful in: Web APIs: For API responses, E-tags help reduce data transfer and ensure clients receive the latest information. Static Content: For web pages, CSS files, and JavaScript assets, Etags prevent redundant downloads, speeding up page loads

be able to add new functionality without altering existing code, typically through inheritance or composition. Liskov Substitution Principle:

Subtypes should be substitutable for their base types. In other words, derived classes should be able to replace their parent classes without affecting the functionality of the application.

Interface Segregation Principle: Clients should not be forced to depend on interfaces they do not use. This encourages the creation of small, specific interfaces, rather than large, general ones, making the design more flexible and reducing coupling.

Dependency Inversion Principle: High-level modules should not depend on low-level modules; both should depend on abstractions. This means code should rely on abstract interfaces rather than concrete implementations, promoting decoupling and making the system easier to extend and maintain.

Caching 1/2

Page caching is a Rails mechanism which allows the request for a generated page to be fulfilled by the web server (i.e. Apache or NGINX) without having to go through the entire Rails stack. While this is super fast it can't be applied to every situation (such as pages that need authentication). Also, because the web server is serving a file directly from the filesystem you will need to implement cache expiraPage Caching cannot be used for actions that have before filters - for example, pages that require authentication. This is where Action Caching comes in. Action Caching works like Page Caching except the incoming web request hits the Rails stack so that before filters can be run on it before the cache is served. This allows authentication and other restrictions to be run while still serving the result of the output from a cached copy.

Caching 1/2 (cont)

Dynamic web applications usually build pages with a variety of components not all of which have the same caching characteristics. When different parts of the page need to be cached and expired separately you can use Fragment Caching. Fragment Caching allows a fragment of view logic to be wrapped in a cache block and served out of the cache store when the next request comes in.

Caching 2/2

Low-level Sometimes you need to cache a particular value or query result instead of caching view fragments. Rails' caching mechanism works great for storing any kind of information.

SQL caching Query caching is a Rails feature that caches the result set returned by each query. If Rails encounters the same query again for that request, it will use the cached result set as opposed to running the query against the database again.

Migrations

Rails provides a set of rake tasks to work with migrations which boil down to running certain sets of migrations. The very first migration related rake task you will use will probably be rake db:migrate. In its most basic form it just runs the up or change method for all the migrations that have not yet been run. If there are no such migrations, it exits. It will run these migrations in order based on the date of the migration.

Migrations (cont)
Note that running the db:migrate
also invokes the db:sch-

scopes

Scoping allows you to specify commonly-used queries(it can be considered as a shortcut for long or most frequently used queries) which can be referenced as method calls on the association objects or models. With these scopes, you can use every method previously covered such as where, joins and includes. All scope methods will return an ActiveRecord::Relation object which will allow for further methods (such as other scopes) to be called on it.

Rack Rack is the underlying technology behind nearly all of the web frameworks in the Ruby world "Rack" is actually a few different things: An architecture - Rack defines a very simple interface, and any code that conforms to this interface can be used in a Rack application. This makes it very easy to build small, focused, and reusable bits of code and then use Rack to compose these bits into a larger application. A Ruby gem - Rack is is distributed as a Ruby gem that provides the glue code needed to compose our code. require "rack" require "thin" class HelloWorld def call(env)

Rack defines a very simple interface. Rack compliant code must have the following three characteristics:

It must respond to call The call method must accept a single argument -

This argument is typically called env or environment, and it bundles all of the data about the request.

The call method must return an array of three elements These elements are, in order,

status for the HTTP status code, headers, and body for the actual content of the response.

Rack (cont)

A nice side effect of the call interface is that procs and lambdas can be used as Rack objects.

Middleware are the building blocks of larger applications built using the Rack pattern. Each middleware is a Rack compatible application, and our final application is built by composing together, or nesting these middleware. Unlike base Rack apps, middleware must be classes as they need to have an initializer which will be passed the next app in the chain. For our first middleware example, we'll introduce a middleware that logs the amount of time the request took and

adds that to the response.

Rack (cont)

To begin, we'll update our core Rack app to sleep for 3 seconds to give us something worth logging, and then we'll build our middleware: Rack::Handler::Thin.run LoggingMiddleware.new(app) Middleware are perfect for nonapp specific logic. Things like setting caching headers, logging, parsing the request object, etc. all are great use cases for Rack middleware. For example, in Rails, cookie parsing, sessions, and param parsing are all handled by Middleware.

optimistic pessimistic locking (cont)

Optimistic locking is a mechanism to prevent data overrides by assuming that a database transaction conflict rarely happens

When one user is editing a record and we maintain an exclusive lock on that record, another user is prevented from modifying this record until the lock is released or the transaction is completed. This explicit locking is known as a pessimistic lock

uses a "version-number" column to track changes in each table that needs to implement concurrent access

Optimistic locking is just a mechanism to prevent processes from overwriting changes by another process. Optimistic locking is not a magic wand to manage or auto-merge any conflicting changes. It can only allow users to alert or notify about such conflicting changes.

optimistic pessimistic locking (cont)

Optimistic locking works by just comparing the value of the "version" column. Thus, optimistic locking is not a real database lock

Advisory Lock

optimistic pessimistic locking (cont)

An advisory lock is a voluntary locking mechanism that requires transactions to explicitly request and release locks on resources. How it works: Transactions explicitly acquire advisory locks on resources, signaling to other transactions that they should also respect these locks. Advisory locks don't inherently block transactions; instead, they rely on voluntary adherence. Use cases: Advisory locks are useful in systems where developers want fine-grained control over concurrency or when specific business logic dictates locking behavior, such as file management systems.

fields.	

Partial Index: create index where condition

The order of columns in a multi-column index affects how well it optimizes queries. Consider these factors: Query Patterns: Place the column most frequently used in queries or filters first. This increases the chances of the index being utilized effectively. Selective Columns: Columns with high selectivity (i.e., a wide range of unique values) should appear first. This maximizes the potential for early filtering. Combining Columns: If queries often filter by a combination of columns, ensure the index order matches the most common query patterns.

Highiest cardinality means better index. Columns with high cardinality have many unique values relative to the total number of rows.

singleton methods, Eigenclass

In Ruby, a class is an object. Indeed, a class is literally an instance of the class Class The eigenclass is an unnamed instance of the class Class attached to an object and which instance methods are used as singleton methods of the defined object.

RubyGems

The RubyGems software allows you to easily download, install, and use ruby software packages on your system.

The software package is called a "gem" which contains a packaged Ruby application or library.

Eigenclass

Every Ruby object has an associated eigenclass, which is created automatically the first time a singleton method (a method defined only for that specific object) is added to it. The eigenclass stores these singleton methods.

Eigenclass (cont)

Eigenclasses can be useful in Rails for extending or modifying specific instances of classes without affecting the class as a whole: Singleton Methods: You might use a singleton method to add behavior directly to an individual object, such as a single instance of a model, without altering its class definition. Meta-Programming: Eigenclasses play a role in meta-programming techniques, allowing for dynamic modifications to objects.

Strong params

Strong Parameters is a feature of Rails that prevents assigning request parameters to objects unless they have been explicitly permitted. It has its own DSL (Domain Specific Language, or in other words, a predefined syntax it understands), that allows you to indicate what parameters should be allowed. It also lets you indicate if each parameter should be a hash, array or scalar (i.e. integer, string, etc.), as well as some to other functionality

yield, content_for (cont)

The best practice is to use yield in your layouts, and content_for in your views. There is a special second use for content_for, where you give it no block and it returns the previously rendered content. This is primarily for use in helper methods where yield cannot work. Within your views, the best practice is to stick to yield :my_content to recall the content, and content_for :my_content do...end to render the content.

What is the primary technique for writing a test

Test actual result of execution, integration tests, rather than only unit tests. Write scenario as a complex test

Eigenclass (cont)

Eigenclasses can be useful in Rails for extending or modifying specific instances of classes without affecting the class as a whole: Singleton Methods: You might use a singleton method to add behavior directly to an individual object, such as a single instance of a model, without altering its class definition. Meta-Programming: Eigenclasses play a role in meta-programming techniques, allowing for dynamic modifications to objects.

`class User < ApplicationRecord</pre> end user = User.find(1) def user.greet "Hello, #{self.name}!" end puts user.greet # Outputs "-Hello, [User's name]!"
