Nursing Mental Health Drugs: Antipsychotics Cheat Sheet by ashley_ap (ashap) via cheatography.com/134446/cs/40243/

First Generation (Conventional) Antipsychotics		
Mode of Action	block dopamine receptors.	
Drugs	Chlorpromazine, Haloperidol, Fluphenazine, Loxapine, Thioridazine	
Side effects	Anticholinergic, sedation, ED, gynecomastia, galactorrhea. substantial weight gain	
Adverse Effect: Extrapyramidal Symptoms (EPS)	Caused by block of dopamine. Must monitor for involuntary movements.	
1) Acute Dystonia	S/S: facial grimacing, involuntary eye movement upward, muscle spasms of face, neck, tongue and back (trunk will arch forward), laryngeal spasms	
2) Pseudopar- kinsonism	S/S: stooped posture, shuffling gait, rigidity, bradykinesia, tremors at rest, pill rolling motion.	
3) Akathisia	S/S: restless, trouble standing still, paces the floor, feet in constant motion, rocking back and forth.	
4) Tardive Dyskinesia	S/S: protrusion/rolling of the tongue, sucking/s- macking of the lips, chewing motion, facial dyskin- esia, involuntary movements of body/extremities.	
If positive for EPS stop medication or add benzatropine (Cogentin)		

Most effective on **Positive symptoms of schizophrenia** that include delusions (fix/false beliefs), hallucinations (visual/ auditory).

Second Generation (unconventional) Antipsychotics	
Mode of Action	Blocks dopamine and serotonin
Clozapine	Considerations: Relatively free of EPS, convulsions are possible.
	Fatal side effect: suppress bone marrow and induces agranulocytosis (lack of WBC). Routine labs weekly for 6 months.
Ripser- idone	Considerations: Highest risk of EPS, sedation & orthostatic hypotension = fall risk. Weight gain, sedation, and sexual dysfunction may lead to non-adherence.
Olanzapine	SE: Sedation, weight gain, hyperglycemia (new onset type 2 DM) and higher risk of metabolic syndrome.
Zipras- idone	CI'D in patients with known hx of QT interval prolon- gation , recent acute MI, uncompromised heart failure. <i>must be taken with food to enable absorption</i>
Ariprazole	Dopamine modulator, can be agonist or antagonist. no weight gain or sedation.
targets positive & negative symptoms of schizophrenia.	

often chosen as first line due to more favorable side effect profile *less EPS* but increased risk of metabolic syndrome (increased weight, hyperglycemia, and elevated triglycerides).

Ripseridone & Olanzapine have injectable long term forms
