

### Linear Regression Cheat Sheet

#### Linear Regression Overview

Linear regression is a statistical technique used to model the relationship between a dependent variable and one or more independent variables.

It assumes a linear relationship between the independent variables and the dependent variable.

#### Simple Linear Regression

Simple linear regression involves a single independent variable ( $x$ ) and a dependent variable ( $y$ ) related by the equation:  $y = mx + c$ , where  $m$  is the slope and  $c$  is the intercept.

#### Multiple Linear Regression

Multiple linear regression involves more than one independent variable ( $x_1, x_2, x_3, \dots$ ) and a dependent variable ( $y$ ) related by the equation:  $y = b_0 + b_1x_1 + b_2x_2 + \dots + b_nx_n$ , where  $b_0$  is the intercept, and  $b_1, b_2, \dots, b_n$  are the coefficients.

#### Assumptions of Linear Regression

**Linearity:** There should be a linear relationship between the independent and dependent variables.

**Independence:** The observations should be independent of each other.

**Homoscedasticity:** The variance of the residuals should be constant across all levels of the independent variables.

**Normality:** The residuals should be normally distributed.

**No multicollinearity:** The independent variables should not be highly correlated with each other.

#### Fitting the Model

### Linear Regression Cheat Sheet (cont)

The goal is to find the best-fitting line that minimizes the sum of squared residuals (differences between predicted and actual values).

This is typically achieved using the method of least squares.

#### Interpreting Coefficients

The intercept ( $b_0$ ) represents the expected value of the dependent variable when all independent variables are zero.

The coefficients ( $b_1, b_2, \dots, b_n$ ) represent the change in the dependent variable associated with a one-unit change in the corresponding independent variable, holding other variables constant.

#### Evaluating Model Performance

**R-squared ( $R^2$ ):** Indicates the proportion of variance in the dependent variable explained by the independent variables. Higher values indicate a better fit.

**Adjusted R-squared:** Similar to R-squared, but adjusts for the number of predictors in the model.

**Root Mean Squared Error (RMSE):** Represents the average prediction error of the model. Lower values indicate better performance.

**Residual Analysis:** Plotting residuals to check for patterns or outliers that violate assumptions.

#### Handling Nonlinearity

### Linear Regression Cheat Sheet (cont)

**Polynomial Regression:** Transforming the independent variables by adding polynomial terms (e.g.,  $x^2, x^3$ ) to capture nonlinear relationships.

**Logarithmic Transformation:** Taking the logarithm of the dependent or independent variables to handle exponential growth or decay.

#### Dealing with Multicollinearity

**Check Correlation:** Identify highly correlated independent variables using correlation matrices or variance inflation factor (VIF) analysis.

**Remove or Combine Variables:** Remove one of the highly correlated variables or combine them into a single variable.

#### Regularization Techniques

**Ridge Regression:** Adds a penalty term to the sum of squared residuals to shrink the coefficients, reducing the impact of multicollinearity.

**Lasso Regression:** Similar to Ridge regression, but with a penalty that can shrink coefficients to zero, effectively performing feature selection.

### Logistic Regression Cheat Sheet

#### Logistic Regression Overview

Logistic regression is a statistical technique used to model the relationship between a dependent variable and one or more independent variables.

It is primarily used for binary classification problems, where the dependent variable takes on two categories

#### Binary Logistic Regression

### Logistic Regression Cheat Sheet (cont)

Binary logistic regression involves a binary dependent variable ( $y$ ) and one or more independent variables ( $x_1, x_2, x_3, \text{etc.}$ ).

The logistic regression equation models the probability of the dependent variable belonging to a specific category.

#### Logistic Regression Equation

The logistic regression equation is represented as:

$p = 1 / (1 + e^{-(z)})$ , where  $p$  is the probability of the event occurring, and  $z$  is the linear combination of the independent variables and their coefficients.

#### Link Function

Logistic regression uses the logistic or sigmoid function as the link function to map the linear combination of independent variables to a probability value between 0 and 1.

#### Estimating Coefficients

Coefficients are estimated using maximum likelihood estimation, which finds the values that maximize the likelihood of the observed data given the model.

The coefficients represent the log-odds ratio, indicating the change in the log-odds of the event occurring for a one-unit change in the independent variable.

#### Interpreting Coefficients

### Logistic Regression Cheat Sheet (cont)

The coefficients can be exponentiated to obtain odds ratios, representing the change in odds of the event occurring for a one-unit change in the independent variable.

Odds ratios greater than 1 indicate a positive association, while those less than 1 indicate a negative association.

#### Evaluating Model Performance

**Accuracy:** The proportion of correctly classified instances.

**Confusion Matrix:** A table showing the true positives, true negatives, false positives, and false negatives.

**Precision:** The proportion of true positives out of all positive predictions ( $TP / (TP + FP)$ ).

**Recall (Sensitivity):** The proportion of true positives out of all actual positives ( $TP / (TP + FN)$ ).

**Specificity:** The proportion of true negatives out of all actual negatives ( $TN / (TN + FP)$ ).

**F1 Score:** A measure that combines precision and recall to balance their importance.

#### Regularization Techniques

**Ridge Regression (L2 regularization):** Adds a penalty term to the loss function to shrink the coefficients, reducing overfitting.

**Lasso Regression (L1 regularization):** Similar to Ridge regression but can shrink coefficients to zero, effectively performing feature selection.

#### Multiclass Logistic Regression

### Logistic Regression Cheat Sheet (cont)

Multiclass logistic regression extends binary logistic regression to handle more than two categories.

One-vs-Rest (OvR) or One-vs-All (OvA) is a common approach where separate binary logistic regression models are trained for each class against the rest.

#### Dealing with Imbalanced Data

**Adjust Class Weights:** Assign higher weights to the minority class to address the class imbalance during model training.

**Resampling Techniques:** Oversampling the minority class or undersampling the majority class to create a balanced dataset.

### k-Nearest Neighbors Cheat Sheet

#### k-Nearest Neighbors Overview

k-Nearest Neighbors is a non-parametric and instance-based machine learning algorithm used for classification and regression tasks.

It predicts the class or value of a new data point based on the majority vote or average of its  $k$  nearest neighbors in the feature space.

#### Choosing $k$

The value of  $k$  represents the number of nearest neighbors to consider when making predictions.

A small value of  $k$  (e.g., 1) may lead to overfitting, while a large value of  $k$  may lead to oversimplification and loss of local patterns.

The optimal value of  $k$  is typically determined through hyperparameter tuning using techniques like cross-validation

#### Distance Metrics

Sponsored by **CrosswordCheats.com**

By **bhaskar**

[cheatography.com/bhaskar/](https://cheatography.com/bhaskar/)

Not published yet.

Last updated 20th June, 2023.

Page 2 of 17.

### k-Nearest Neighbors Cheat Sheet (cont)

**Euclidean Distance:** Calculates the straight-line distance between two points in the feature space.

**Manhattan Distance:** Calculates the sum of absolute differences between the coordinates of two points.

Other distance metrics like Minkowski, Cosine, and Hamming distance can also be used depending on the data type and problem domain.

### Feature Scaling

It's crucial to scale the features before applying k-NN, as it is sensitive to the scale of the features.

Standardization (mean = 0, standard deviation = 1) or normalization (scaling to a range) techniques like min-max scaling are commonly used.

### Handling Categorical Features

Categorical features must be encoded into numerical values before applying k-NN.

**One-Hot Encoding:** Creates binary dummy variables for each category, representing their presence or absence.

**Label Encoding:** Assigns a unique numerical label to each category.

### Classifying New Instances

For classification tasks, the class of a new instance is determined by the majority class among its k nearest neighbors.

**Voting Mechanisms:** Simple majority vote, weighted vote (based on distance or confidence), or distance-weighted vote (inverse of distance) can be used.

### Regression with k-NN

### k-Nearest Neighbors Cheat Sheet (cont)

For regression tasks, the predicted value of a new instance is typically the average (mean or median) of the target values of its k nearest neighbors.

### Model Evaluation

**Accuracy:** Proportion of correctly classified instances for classification tasks.

**Mean Squared Error (MSE):** Average of the squared differences between the predicted and actual values for regression tasks.

**Cross-Validation:** Technique to assess the performance of the k-NN model by splitting the data into multiple folds.

### Curse of Dimensionality

As the number of features increases, the feature space becomes increasingly sparse, making k-NN less effective.

Feature selection or dimensionality reduction techniques (e.g., Principal Component Analysis) can help mitigate this issue.

### Advantages and Limitations

**Advantages:** Simplicity, no assumptions about data distribution, and ability to capture complex patterns.

**Limitations:** Computationally expensive for large datasets, sensitivity to feature scaling, and inability to handle missing values well.

### Support Vector Machines Cheat Sheet

#### Support Vector Machines Overview

Support Vector Machines is a supervised machine learning algorithm used for classification and regression tasks.

It finds an optimal hyperplane that maximally separates or fits the data points in the feature space.

### Support Vector Machines Cheat Sheet (cont)

#### Linear SVM

Linear SVM constructs a linear decision boundary to separate data points of different classes.

It aims to maximize the margin, which is the perpendicular distance between the decision boundary and the nearest data points (support vectors).

#### Kernel Trick

The kernel trick allows SVMs to efficiently handle non-linearly separable data by mapping the data to a higher-dimensional feature space.

Common kernel functions include Linear, Polynomial, Radial Basis Function (RBF), and Sigmoid.

#### Soft Margin SVM

Soft Margin SVM allows for some misclassification in order to achieve a more flexible decision boundary.

It introduces a regularization parameter (C) to control the trade-off between maximizing the margin and minimizing misclassification.

#### Choosing the Right Kernel

**Linear Kernel:** Suitable for linearly separable data or when the number of features is large compared to the number of samples.

**Polynomial Kernel:** Suitable for problems with intermediate complexity and higher-order polynomial relationships.

**RBF Kernel:** Suitable for complex and non-linear relationships; the most commonly used kernel.

**Sigmoid Kernel:** Suitable for problems influenced by logistic regression or neural networks.

#### Model Training and Optimization

Sponsored by **CrosswordCheats.com**  
Learn to solve cryptic crosswords!  
<http://crosswordcheats.com>

### Support Vector Machines Cheat Sheet (cont)

SVM training involves solving a quadratic programming problem to find the optimal hyperplane.

The optimization process can be computationally expensive for large datasets, but various optimization techniques (e.g., Sequential Minimal Optimization) can improve efficiency.

#### Tuning Parameters

**C (Regularization Parameter):** Controls the trade-off between misclassification and the width of the margin. A smaller C allows more misclassification, while a larger C enforces stricter classification.

**Gamma (Kernel Coefficient):** Influences the shape of the decision boundary. A higher gamma value leads to a more complex decision boundary.

#### Multi-Class Classification

One-vs-Rest (OvR) or One-vs-One (OvO) strategies can be used to extend SVM to multi-class classification problems.

**OvR:** Trains separate binary classifiers for each class against the rest.

**OvO:** Trains a binary classifier for every pair of classes

#### Handling Imbalanced Data

Class imbalance can affect SVM performance. Techniques such as resampling (undersampling or oversampling) and adjusting class weights can help address this issue.

#### Advantages and Limitations

### Support Vector Machines Cheat Sheet (cont)

**Advantages:** Effective in high-dimensional spaces, robust against overfitting, and suitable for both linear and non-linear classification.

**Limitations:** Computationally intensive for large datasets, sensitive to hyperparameter tuning, and challenging to interpret complex models.

### Decision Tree Cheat Sheet

#### Decision Tree Overview

Decision Trees are a supervised machine learning algorithm used for classification and regression tasks.

They learn a hierarchical structure of decisions and conditions from the data to make predictions.

#### Tree Construction

Decision Trees are constructed through a top-down, recursive partitioning process called recursive binary splitting.

The algorithm selects the best feature at each node to split the data based on certain criteria (e.g., information gain, Gini impurity).

#### Splitting Criteria

**Information Gain:** Measures the reduction in entropy (or increase in information) achieved by splitting on a particular feature.

**Gini Impurity:** Measures the probability of misclassifying a randomly chosen element if it were labeled randomly according to the class distribution.

#### Handling Continuous and Categorical Features

Not published yet.

Last updated 20th June, 2023.

Page 4 of 17.

### Decision Tree Cheat Sheet (cont)

For continuous features, decision tree algorithms use threshold values to split the data.

For categorical features, each category forms a separate branch in the decision tree.

#### Tree Pruning

Pruning is a technique used to avoid overfitting by reducing the complexity of the decision tree.

**Pre-pruning:** Setting constraints on tree depth, minimum samples per leaf, or maximum number of leaf nodes during tree construction.

**Post-pruning:** Removing or collapsing branches that provide little information gain or result in minimal improvements in performance.

#### Handling Missing Values

Decision Trees can handle missing values by treating them as a separate category or by imputing missing values before tree construction.

#### Handling Imbalanced Data

Imbalanced class distributions can bias the decision tree. Techniques like class weighting, undersampling, or oversampling can help address this issue.

#### Feature Importance

Decision Trees provide feature importance scores based on how much each feature contributes to the overall split decisions.

Importance can be measured by the total reduction in impurity or the total information gain associated with a feature

#### Ensemble Methods

### Decision Tree Cheat Sheet (cont)

Random Forest: An ensemble of decision trees where each tree is trained on a random subset of the data with replacement. It reduces overfitting and improves performance.

Gradient Boosting: Builds an ensemble by sequentially adding decision trees, with each tree correcting the mistakes made by the previous trees.

#### Advantages and Limitations

Advantages: Easy to understand and interpret, handles both numerical and categorical data, and can capture non-linear relationships.

Limitations: Prone to overfitting, sensitive to small changes in data, and may not generalize well to unseen data if the tree structure is too complex.

### Random Forest Cheat Sheet

#### Random Forest Overview

Random Forest is an ensemble learning algorithm that combines multiple decision trees to make predictions.

It is used for both classification and regression tasks and improves upon the individual decision trees' performance and robustness.

#### Ensemble of Decision Trees

Random Forest creates an ensemble by constructing a set of decision trees on random subsets of the training data (bootstrap sampling).

Each decision tree is trained independently, making predictions based on majority voting (classification) or averaging (regression) of the individual tree predictions.

#### Random Feature Subsets

### Random Forest Cheat Sheet (cont)

In addition to using random subsets of the training data, Random Forest also considers a random subset of features at each node for constructing the decision trees.

This randomness reduces the correlation between trees and promotes diversity, leading to improved generalization.

#### Building Decision Trees

Each decision tree in the Random Forest is constructed using a subset of the training data and a subset of the available features.

Tree construction follows the usual process of recursive binary splitting based on criteria like information gain or Gini impurity.

#### Feature Importance

Random Forest provides a measure of feature importance based on how much each feature contributes to the ensemble's predictive performance.

Importance can be calculated by evaluating the average decrease in impurity or the average decrease in a split criterion (e.g., Gini index) caused by a feature.

#### Out-of-Bag (OOB) Error

Random Forest uses the out-of-bag samples (not included in the bootstrap sample) to estimate the model's performance without the need for cross-validation.

OOB error provides a good estimate of the model's generalization performance and can be used for model evaluation and hyperparameter tuning.

#### Hyperparameter Tuning

### Random Forest Cheat Sheet (cont)

Important hyperparameters to consider when working with Random Forests include the number of trees (`n_estimators`), maximum depth of each tree (`max_depth`), minimum samples required to split a node (`min_samples_split`), and maximum number of features to consider for each split (`max_features`).

#### Handling Imbalanced Data

Random Forests can handle imbalanced data by adjusting class weights during tree construction or by using sampling techniques like oversampling the minority class or undersampling the majority class.

#### Advantages and Limitations

Advantages: Robust to overfitting, can handle high-dimensional data, provides feature importance, and performs well on various types of problems.

Limitations: Requires more computational resources than individual decision trees, can be slower to train and predict, and may not perform well on extremely imbalanced datasets.

#### Applications

Random Forests are commonly used in various domains, including classification tasks such as image recognition, text classification, fraud detection, and regression tasks like predicting housing prices or stock market trends.

### Gradient Boosting Cheat Sheet

#### Gradient Boosting Overview

### Gradient Boosting Cheat Sheet (cont)

Gradient Boosting is an ensemble learning algorithm that combines multiple weak prediction models (typically decision trees) to create a strong predictive model.

It is used for both classification and regression tasks and sequentially improves the model's performance by minimizing the errors of the previous models.

#### Boosting Process

Gradient Boosting builds the ensemble by adding decision trees sequentially, with each subsequent tree correcting the mistakes of the previous ones.

The trees are built in a greedy manner, minimizing a loss function (e.g., mean squared error for regression, log loss for classification) at each step.

#### Gradient Descent

Gradient Boosting optimizes the loss function using gradient descent.

The model calculates the negative gradient of the loss function with respect to the current model's predictions and fits a new weak learner to this gradient.

#### Learning Rate and Number of Trees

The learning rate (shrinkage factor) controls the contribution of each tree to the ensemble. A smaller learning rate requires more trees for convergence but can lead to better generalization.

The number of trees (iterations) determines the complexity of the model and affects both training time and the risk of overfitting.

#### Regularization Techniques

### Gradient Boosting Cheat Sheet (cont)

Regularization is applied to control the complexity of the model and avoid overfitting.

**Tree Depth:** Restricting the maximum depth of each tree can prevent overfitting and speed up training.

**Tree Pruning:** Applying pruning techniques to remove branches with little contribution to the model's performance.

#### Feature Subsampling

Gradient Boosting can use random feature subsets similar to Random Forests to introduce randomness and increase diversity among the weak learners.

It can prevent overfitting when dealing with high-dimensional data or datasets with a large number of features.

#### Handling Imbalanced Data

Techniques such as class weighting or sampling (undersampling the majority class or oversampling the minority class) can be applied to address imbalanced datasets during Gradient Boosting.

#### Hyperparameter Tuning

Important hyperparameters to consider when working with Gradient Boosting include the learning rate, number of trees, maximum depth of each tree, and regularization parameters like `subsample` and `colsample_bytree`.

#### Early Stopping

### Gradient Boosting Cheat Sheet (cont)

Early stopping is a technique used to prevent overfitting and speed up training by monitoring the model's performance on a validation set.

Training stops when the performance on the validation set does not improve for a specified number of iterations.

#### Applications

Gradient Boosting has been successfully applied to a wide range of tasks, including web search ranking, anomaly detection, click-through rate prediction, and personalized medicine.

### Naive Bayes Cheat Sheet

#### Naive Bayes Overview

Naive Bayes is a probabilistic machine learning algorithm based on Bayes' theorem with the assumption of independence between features.

It is primarily used for classification tasks and is efficient, simple, and often works well in practice.

#### Bayes' Theorem

Bayes' theorem calculates the posterior probability of a class given the observed evidence.

$$P(\text{Class}|\text{Features}) = \frac{P(\text{Features}|\text{Class}) * P(\text{Class})}{P(\text{Features})}$$

#### Assumption of Feature Independence

Naive Bayes assumes that the features are conditionally independent given the class label, which is a simplifying assumption to make the calculations more tractable.

Despite this assumption rarely being true in reality, Naive Bayes can still perform well in practice.

### Naive Bayes Cheat Sheet (cont)

#### Types of Naive Bayes Classifiers

**Gaussian Naive Bayes:** Assumes a Gaussian distribution for continuous features and estimates the mean and variance for each class.

**Multinomial Naive Bayes:** Suitable for discrete features, typically used for text classification tasks, where features represent word frequencies.

**Bernoulli Naive Bayes:** Similar to multinomial, but assumes binary features (presence or absence).

#### Feature Probability Estimation

For continuous features, Gaussian Naive Bayes estimates the mean and variance for each class.

For discrete features, Multinomial Naive Bayes estimates the probability of each feature occurring in each class.

For binary features, Bernoulli Naive Bayes estimates the probability of each feature being present in each class.

#### Handling Zero Probabilities

The Naive Bayes classifier may encounter zero probabilities if a particular feature does not occur in the training set for a specific class.

To handle this, techniques like Laplace smoothing or add-one smoothing can be applied to avoid zero probabilities.

#### Handling Continuous Features

Gaussian Naive Bayes assumes a Gaussian distribution for continuous features.

Continuous features can be discretized into bins or transformed into categorical variables before using Naive Bayes.

#### Text Classification with Naive Bayes

### Naive Bayes Cheat Sheet (cont)

Naive Bayes is commonly used for text classification tasks, such as spam detection or sentiment analysis.

Text data is typically preprocessed by tokenization, removing stop words, and applying techniques like TF-IDF or Bag-of-Words representation before using Naive Bayes.

#### Advantages and Limitations

**Advantages:** Simplicity, efficiency, and can handle high-dimensional data well.

**Limitations:** Strong independence assumption may not hold in reality, and it can be sensitive to irrelevant features. It may struggle with rare or unseen combinations of features.

#### Handling Imbalanced Data

Naive Bayes can face challenges with imbalanced datasets where the class distribution is skewed.

Techniques like class weighting or resampling (undersampling or oversampling) can help alleviate the impact of imbalanced data.

### Principal Component Analysis Cheat Sheet

#### PCA Overview

PCA is a dimensionality reduction technique used to transform a high-dimensional dataset into a lower-dimensional space.

It identifies the principal components, which are orthogonal directions that capture the maximum variance in the data.

#### Variance and Covariance

### Principal Component Analysis Cheat Sheet (cont)

PCA is based on the variance-covariance matrix or the correlation matrix of the dataset.

Variance measures the spread of data along a specific axis, while covariance measures the relationship between two variables.

#### Steps in PCA

**Standardize the data:** PCA works best with standardized data to ensure equal importance across different variables.

**Calculate the covariance matrix or correlation matrix:** This represents the relationships between the variables in the dataset.

**Compute the eigenvectors and eigenvalues:** These eigenvectors represent the principal components, and the corresponding eigenvalues indicate the amount of variance explained by each component.

**Select the desired number of principal components:** Choose the top components that explain the majority of the variance in the data.

**Transform the data:** Project the original data onto the selected principal components to obtain the lower-dimensional representation.

#### Explained Variance and Scree Plot

Explained variance ratio indicates the proportion of variance explained by each principal component.

A scree plot visualizes the explained variance ratio for each component, helping to determine the number of components to retain.

#### Dimensionality Reduction and Reconstruction

### Principal Component Analysis Cheat Sheet (cont)

PCA reduces the dimensionality of the dataset by selecting a subset of principal components.

Reconstruction of the original data is possible by projecting the lower-dimensional representation back into the original feature space.

#### Applications of PCA

Dimensionality reduction: PCA can help visualize high-dimensional data, reduce noise, and eliminate redundant or correlated features.

Data compression: PCA can compress the data by retaining only the most important components.

Feature extraction: PCA can extract meaningful features from complex data, facilitating subsequent analysis.

#### Interpretation of Principal Components

Principal components are linear combinations of the original features.

The direction of a principal component represents the most significant variation in the data.

The magnitude of the component's loading on a particular feature indicates its contribution to that component.

#### Assumptions and Limitations

PCA assumes linear relationships between variables and requires variables to be continuous or approximately continuous.

It may not be suitable for datasets with nonlinear relationships or when interpretability of individual features is essential.

#### Extensions to PCA

### Principal Component Analysis Cheat Sheet (cont)

Kernel PCA: An extension that allows nonlinear transformations of the data.

Sparse PCA: A variant that encourages sparsity in the loadings, resulting in a more interpretable representation.

#### Implementation and Libraries

PCA is implemented in various programming languages. Commonly used libraries include scikit-learn (Python), caret (R), and numpy (Python) for numerical computations.

### Cluster Analysis Cheat Sheet

#### Cluster Analysis Overview

Cluster Analysis is an unsupervised learning technique used to group similar objects or data points into clusters based on their characteristics or proximity.

It helps discover hidden patterns, similarities, or structures within the data.

#### Types of Cluster Analysis

Hierarchical Clustering: Builds a hierarchy of clusters by recursively merging or splitting clusters based on a similarity measure.

K-means Clustering: Divides the data into a predetermined number (k) of non-overlapping clusters by minimizing the within-cluster sum of squares.

Density-based Clustering: Groups data points based on density and identifies regions with higher density as clusters.

Model-based Clustering: Assumes a specific statistical model for each cluster and estimates model parameters to assign data points to clusters.

#### Similarity and Distance Measures

Not published yet.  
Last updated 20th June, 2023.  
Page 8 of 17.

### Cluster Analysis Cheat Sheet (cont)

Cluster analysis often relies on similarity or distance measures to determine the proximity between data points.

Common distance measures include Euclidean distance, Manhattan distance, and cosine similarity.

#### Hierarchical Clustering

Agglomerative (Bottom-Up): Starts with each data point as a separate cluster and iteratively merges the closest pairs of clusters until all points belong to a single cluster.

Divisive (Top-Down): Begins with all data points in one cluster and recursively splits clusters until each data point is in its own cluster.

#### K-means Clustering

Randomly initializes k cluster centroids, assigns each data point to the nearest centroid, recalculates the centroids based on the mean of assigned points, and repeats until convergence.

The choice of the number of clusters (k) is important and can impact the results.

#### Density-based Clustering (DBSCAN)

Density-based Spatial Clustering of Applications with Noise (DBSCAN) groups data points based on density and identifies core points, border points, and noise points.

It defines clusters as dense regions separated by sparser areas and does not require specifying the number of clusters in advance.

#### Model-based Clustering (Gaussian Mixture Models)

### Cluster Analysis Cheat Sheet (cont)

Gaussian Mixture Models (GMM) assume that the data points are generated from a mixture of Gaussian distributions.

It estimates the parameters of the Gaussian distributions and assigns data points to clusters based on the likelihood.

#### Evaluation of Clustering

Internal Evaluation: Measures the quality of clustering using intrinsic criteria such as the silhouette coefficient or within-cluster sum of squares.

External Evaluation: Compares the clustering results to a known ground truth, if available, using external criteria like purity or F-measure.

#### Handling Missing Data and Outliers

Missing data can be handled by imputation techniques before clustering.

Outliers can significantly impact clustering results. Techniques like outlier detection or preprocessing methods can be applied to mitigate their influence.

#### Visualization of Clustering Results

Dimensionality reduction techniques like PCA or t-SNE can be used to visualize high-dimensional clustering results in lower-dimensional space.

Scatter plots, heatmaps, or dendrograms can provide insights into the clustering structure.

### Neural Networks Cheat Sheet

#### Neural Network Basics

### Neural Networks Cheat Sheet (cont)

Neural networks are a class of machine learning models inspired by the human brain's structure and functioning.

They consist of interconnected nodes called neurons, organized in layers (input, hidden, and output).

#### Activation Functions

Activation functions introduce non-linearity to the neural network and help model complex relationships.

Common activation functions include sigmoid, tanh, ReLU, and softmax (for multiclass classification).

#### Forward Propagation

Forward propagation is the process of passing input data through the neural network to obtain predictions.

Each neuron applies a weighted sum of inputs, followed by the activation function, to produce an output.

#### Loss Functions

Loss functions quantify the difference between predicted outputs and true labels.

Regression: Mean Squared Error (MSE), Mean Absolute Error (MAE).

Binary Classification: Binary Cross-Entropy.

Multiclass Classification: Categorical Cross-Entropy.

#### Backpropagation

Backpropagation is used to update the weights of the neural network based on the calculated gradients of the loss function.

It propagates the error from the output layer to the previous layers, adjusting the weights through gradient descent.

### Neural Networks Cheat Sheet (cont)

#### Gradient Descent Optimization

Gradient Descent is an optimization algorithm used to minimize the loss function and update the weights iteratively.

Common variants include Stochastic Gradient Descent (SGD), Mini-Batch Gradient Descent, and Adam.

#### Regularization Techniques

Regularization helps prevent overfitting and improves the generalization of the neural network.

Common techniques include L1 and L2 regularization (weight decay), dropout, and early stopping.

#### Hyperparameter Tuning

Neural networks have various hyperparameters that need to be tuned for optimal performance.

Examples include learning rate, number of layers, number of neurons per layer, batch size, and activation functions.

#### Convolutional Neural Networks (CNN)

CNNs are specialized neural networks commonly used for image and video processing tasks.

They consist of convolutional layers, pooling layers, and fully connected layers, exploiting the spatial structure of data.

#### Recurrent Neural Networks (RNN)

RNNs are designed for sequential data processing tasks, such as natural language processing and time series analysis.

They have recurrent connections that allow information to persist and flow across different time steps.

#### Transfer Learning

### Neural Networks Cheat Sheet (cont)

Transfer learning leverages pre-trained neural network models on large datasets for similar tasks to improve performance on smaller datasets.

By using pre-trained models as a starting point, training time can be reduced, and generalization can be enhanced.

#### Hardware Acceleration

To speed up training and inference, specialized hardware like GPUs (Graphics Processing Units) or TPUs (Tensor Processing Units) can be utilized.

### Convolutional Neural Networks Cheat Sheet

#### Convolutional Neural Networks Overview

CNNs are a type of neural network specifically designed for processing grid-like data, such as images.

They leverage the concept of convolution to extract relevant features from the input data.

#### Convolutional Layers

Convolutional layers perform the main feature extraction in CNNs.

Each layer consists of multiple filters (also called kernels) that scan the input data through convolution operations.

Convolution applies a sliding window over the input and performs element-wise multiplication and summing to produce feature maps.

#### Pooling Layers

### Convolutional Neural Networks Cheat Sheet (cont)

Pooling layers reduce the spatial dimensions of the feature maps, reducing computational complexity and providing spatial invariance.

Common types of pooling include Max Pooling (selecting the maximum value in each pooling region) and Average Pooling (taking the average).

#### Activation Functions

Activation functions introduce non-linearity to the CNN and enable modeling complex relationships.

ReLU (Rectified Linear Unit) is commonly used as the activation function in CNNs, promoting faster convergence and avoiding the vanishing gradient problem.

#### Fully Connected Layers

Fully connected layers, also known as dense layers, are traditional neural network layers where each neuron is connected to every neuron in the previous layer.

They provide the final classification or regression output by combining the learned features.

#### Loss Functions

Loss functions quantify the difference between predicted outputs and true labels in CNNs.

Common loss functions include Mean Squared Error (MSE) for regression tasks and Cross-Entropy for classification tasks.

#### Training Techniques

Not published yet.  
Last updated 20th June, 2023.  
Page 10 of 17.

### Convolutional Neural Networks Cheat Sheet (cont)

CNNs are typically trained using backpropagation and gradient descent optimization methods.

Techniques like Dropout (randomly deactivating neurons during training) and Batch Normalization (normalizing inputs to accelerate training) are commonly used to improve generalization and performance.

#### Data Augmentation

Data augmentation techniques help increase the diversity of the training data by applying transformations such as rotations, translations, flips, or scaling.

This helps improve the model's ability to generalize and reduces overfitting.

#### Transfer Learning

Transfer learning leverages pretrained CNN models on large datasets and adapts them to new tasks or smaller datasets.

Pretrained models like VGGNet and ResNet are available, allowing transfer of learned features to new applications.

#### Object Localization and Detection

CNNs can be extended to perform object localization and detection tasks using techniques like bounding box regression and region proposal networks (RPN).

#### Semantic Segmentation

Semantic segmentation assigns a label to each pixel or region in an image, allowing detailed object-level understanding.

Fully Convolutional Networks (FCNs) are commonly used for semantic segmentation.

#### Hardware Acceleration

### Convolutional Neural Networks Cheat Sheet (cont)

CNNs can benefit from specialized hardware like GPUs (Graphics Processing Units) or TPUs (Tensor Processing Units) for faster training and inference.

### Recurrent Neural Networks Cheat Sheet

#### Recurrent Neural Network (RNN) Basics

RNNs are a class of neural networks designed for processing sequential data, such as time series, natural language, and speech.

They have recurrent connections that allow information to persist and flow across different time steps

#### RNN Cell

The basic building block of an RNN is the RNN cell, which maintains a hidden state and takes input at each time step.

The hidden state captures the memory of past inputs and influences future predictions.

#### Vanishing and Exploding Gradients

RNNs can suffer from the vanishing gradient problem, where gradients diminish exponentially as they propagate through time, leading to difficulties in learning long-term dependencies.

Conversely, exploding gradients can occur when gradients grow rapidly during backpropagation.

#### Long Short-Term Memory (LSTM)

LSTMs are a type of RNN that address the vanishing gradient problem by using gating mechanisms.

They introduce memory cells, input gates, output gates, and forget gates to selectively remember or forget information.

#### Gated Recurrent Unit (GRU)

### Recurrent Neural Networks Cheat Sheet (cont)

GRUs are another type of RNN that address the vanishing gradient problem and have a simpler architecture compared to LSTMs.

They use reset and update gates to control the flow of information through the network.

#### Bidirectional RNNs

Bidirectional RNNs process the input sequence in both forward and backward directions, capturing information from past and future contexts.

They are useful when the current prediction depends on both past and future context.

#### Sequence-to-Sequence Models

Sequence-to-sequence models, often built with RNNs, are used for tasks such as machine translation, text summarization, and speech recognition.

They encode the input sequence into a fixed-size representation (context vector) and decode it to generate the output sequence.

#### Attention Mechanism

Attention mechanisms enhance the capability of RNNs by selectively focusing on different parts of the input sequence.

They assign different weights to each input element, emphasizing more relevant information during decoding or generating.

#### Training and Backpropagation Through Time (BPTT)

RNNs are trained using BPTT, which extends backpropagation to handle sequences.

BPTT unfolds the RNN through time, allowing error gradients to be calculated and applied to update the weights.

### Recurrent Neural Networks Cheat Sheet (cont)

#### Applications of RNNs

Language modeling, text generation, and sentiment analysis.

Machine translation and natural language understanding.

Speech recognition and speech synthesis. Time series forecasting and anomaly detection.

#### Handling Variable-Length Inputs

Techniques like padding, masking, and sequence bucketing can be used to handle inputs of different lengths in RNNs.

#### Hardware Acceleration

RNNs, especially LSTMs and GRUs, can benefit from specialized hardware like GPUs (Graphics Processing Units) or TPUs (Tensor Processing Units) for faster training and inference.

### Generative Adversarial Networks Cheat Sheet

#### Generative Adversarial Networks (GAN) Basics

GANs are a class of deep learning models composed of two components: a generator and a discriminator.

The generator learns to generate synthetic data samples that resemble real data, while the discriminator tries to distinguish between real and fake samples.

#### Generator

The generator takes random noise as input and generates synthetic samples.

It typically consists of one or more layers of neural networks, often using transpose convolutions for upsampling.

#### Discriminator

### Generative Adversarial Networks Cheat Sheet (cont)

The discriminator takes a sample as input and estimates the probability of it being real or fake.

It typically consists of one or more layers of neural networks, often using convolutions for feature extraction.

#### Adversarial Training

The generator and discriminator are trained in an adversarial manner.

The generator tries to generate samples that fool the discriminator, while the discriminator aims to correctly classify real and fake samples.

#### Loss Functions

The generator and discriminator are trained using different loss functions.

The generator's loss function encourages the generated samples to be classified as real by the discriminator.

The discriminator's loss function penalizes misclassifying real and fake samples.

#### Mode Collapse

Mode collapse occurs when the generator produces limited and repetitive samples, failing to capture the diversity of the real data distribution.

Techniques like minibatch discrimination and feature matching can help alleviate mode collapse.

#### Deep Convolutional GAN (DCGAN)

### Generative Adversarial Networks Cheat Sheet (cont)

DCGAN is a popular GAN architecture that uses convolutional neural networks for both the generator and discriminator.

It leverages convolutional and transpose convolutional layers to generate and discriminate images.

#### Conditional GAN (cGAN)

cGANs introduce additional information (such as class labels) to guide the generation process.

The generator and discriminator take both random noise and conditional information as input.

#### Evaluation of GANs

Evaluating GANs is challenging as there is no direct objective function to optimize.

Common evaluation methods include visual inspection, Inception Score, Fréchet Inception Distance (FID), and Precision and Recall curves.

#### Unsupervised Representation Learning

GANs can learn meaningful representations without explicit labels.

By training on a large unlabeled dataset, the generator can capture and generate high-level features.

#### Variational Autoencoder (VAE) vs. GAN

VAEs and GANs are both generative models but differ in their underlying principles.

VAEs focus on learning latent representations and reconstruction, while GANs emphasize generating realistic samples.

#### Applications of GANs

Not published yet.

Last updated 20th June, 2023.

### Generative Adversarial Networks Cheat Sheet (cont)

Image synthesis and generation.

Style transfer and image-to-image translation.

Data augmentation and synthesis for training other models.

Text-to-image synthesis and generation.

### Transfer Learning Cheat Sheet

#### What is Transfer Learning?

Transfer learning is a technique in machine learning where knowledge gained from training one model is applied to another related task or dataset.

It leverages pre-trained models and their learned representations to improve performance and reduce the need for extensive training on new datasets.

#### Benefits of Transfer Learning

Reduces the need for large labeled datasets for training new models.

Saves computational resources and time required for training.

Helps generalize learned features to new tasks or domains.

Improves model performance, especially with limited data.

#### Popular Pre-trained Models

Image Classification: VGG, ResNet, Inception, MobileNet, EfficientNet.

Natural Language Processing: Word2Vec, GloVe, BERT, GPT, Transformer.

#### Steps for Transfer Learning

### Transfer Learning Cheat Sheet (cont)

**Select a pre-trained model:** Choose a model that was trained on a large dataset and is suitable for your task.

**Remove the top layers:** Remove the final layers responsible for task-specific predictions.

**Feature Extraction:** Extract features from the pre-trained model by passing your dataset through the remaining layers.

**Add new layers:** Add new layers to the pre-trained model to adapt it to your specific task.

**Train the new model:** Fine-tune the new layers with your labeled dataset while keeping the pre-trained weights fixed or updating them with a smaller learning rate.

**Evaluate and Iterate:** Evaluate the performance of your model on a validation set and iterate on the architecture or hyperparameters if necessary.

### Transfer Learning Techniques

**Feature Extraction:** Extract high-level features from the pre-trained model and add new layers for task-specific predictions.

**Fine-tuning:** Fine-tune the pre-trained model's weights by updating them during training with a smaller learning rate.

### Data Augmentation

Apply data augmentation techniques such as rotation, translation, scaling, flipping, or cropping to increase the diversity of your training data.

Data augmentation helps prevent overfitting and improves generalization.

### Domain Adaptation

### Transfer Learning Cheat Sheet (cont)

Domain adaptation is a form of transfer learning where the source and target domains differ, requiring adjustments to make the model generalize well.

Techniques like adversarial training, self-training, or domain-specific fine-tuning can be used for domain adaptation.

### Choosing Layers for Transfer

Earlier layers in a pre-trained model learn low-level features like edges and textures, while later layers learn high-level features.

For small datasets, it's often beneficial to use earlier layers for transfer, as they capture more general features.

### Size of Training Data

The size of the new dataset influences the amount of transfer learning required.

With limited data, it's crucial to rely more on the pre-trained weights and perform minimal fine-tuning to avoid overfitting.

### Transfer Learning in Different Domains

Transfer learning is applicable across various domains, including computer vision, natural language processing, audio processing, and more.

The choice of pre-trained models and the techniques used may vary based on the specific domain.

### Avoiding Negative Transfer

Negative transfer occurs when the knowledge from the source task hinders the performance on the target task.

It can be mitigated by selecting a source task that is related or has shared underlying patterns with the target task.

### Transfer Learning Cheat Sheet (cont)

### Model Evaluation

Evaluate the performance of the transfer learning model using appropriate metrics for your specific task, such as accuracy, precision, recall, F1-score, or mean squared error.

### Reinforcement Learning Cheat Sheet

### Reinforcement Learning Basics

RL is a branch of machine learning where an agent learns to interact with an environment to maximize a reward signal.

The agent learns through a trial-and-error process, taking actions and receiving feedback from the environment.

### Key Components

**Agent:** The learner or decision-maker that interacts with the environment.

**Environment:** The external system with which the agent interacts.

**State:** The current representation of the environment at a particular time step.

**Action:** The decision or choice made by the agent based on the state.

**Reward:** The feedback signal that the agent receives from the environment after taking an action.

### Markov Decision Process (MDP)

MDP provides a mathematical framework for modeling RL problems with states, actions, rewards, and state transitions.

It assumes the Markov property, where the future state depends only on the current state and action, disregarding the history.

### Value Function

### Reinforcement Learning Cheat Sheet (cont)

The value function estimates the expected return or cumulative reward an agent will receive from a particular state or state-action pair.

Value functions can be represented as state-value functions ( $V(s)$ ) or action-value functions ( $Q(s, a)$ ).

#### Policy

The policy determines the agent's behavior, mapping states to actions.

It can be deterministic or stochastic, providing the agent's action selection strategy.

#### Exploration vs. Exploitation

Exploration refers to the agent's search for new actions or states to gather more information about the environment.

Exploitation refers to the agent's tendency to choose actions that are expected to yield the highest immediate rewards based on its current knowledge.

#### Temporal Difference (TD) Learning

TD learning is a method for updating value functions based on the difference between the estimated and actual rewards received.

Q-learning and SARSA are popular TD learning algorithms.

#### Policy Gradient Methods

Policy gradient methods directly optimize the policy by updating its parameters based on the gradients of expected rewards.

They use techniques like REINFORCE, Proximal Policy Optimization (PPO), and Trust Region Policy Optimization (TRPO).

#### Exploration Techniques

### Reinforcement Learning Cheat Sheet (cont)

Epsilon-Greedy: Randomly selects a random action with a probability epsilon to encourage exploration.

Upper Confidence Bound (UCB): Balances exploration and exploitation using an optimistic value estimate.

Thompson Sampling: Selects actions based on random samples from the posterior distribution of action values.

#### Deep Reinforcement Learning (DRL)

DRL combines RL with deep neural networks to handle high-dimensional state spaces and complex tasks.

Deep Q-Networks (DQN) and Deep Deterministic Policy Gradient (DDPG) are popular DRL algorithms.

#### Off-Policy vs. On-Policy

Off-policy methods learn the value function or policy using data collected from a different policy.

On-policy methods learn from the direct interaction of the agent with the environment.

#### Model-Based vs. Model-Free

Model-based methods learn a model of the environment to plan and make decisions.

Model-free methods directly learn the optimal policy or value function without explicitly modeling the environment dynamics.

### Time Series Forecasting Cheat Sheet

#### Time Series Basics

Time series data is a sequence of observations collected over time, typically at regular intervals.

It exhibits temporal dependencies, trends, seasonality, and may contain noise.

#### Stationarity

Not published yet.

Last updated 20th June, 2023.

Page 14 of 17.

### Time Series Forecasting Cheat Sheet (cont)

Stationary time series have constant mean, variance, and autocovariance over time.

Stationarity is desirable for accurate forecasting.

#### Trends and Seasonality

Trend refers to the long-term upward or downward movement in a time series.

Seasonality refers to patterns that repeat at fixed intervals.

Identifying and handling trends and seasonality is important for accurate forecasting.

#### Autocorrelation Function (ACF) and Partial Autocorrelation Function (PACF)

ACF measures the correlation between a time series and its lagged values.

PACF measures the correlation between a time series and its lagged values, excluding the intermediate lags.

They help identify the order of autoregressive (AR) and moving average (MA) components in time series models.

#### Time Series Models

Autoregressive Integrated Moving Average (ARIMA): A linear model that combines AR and MA components to handle stationary time series.

Seasonal ARIMA (SARIMA): Extends ARIMA to handle seasonal time series data.

Exponential Smoothing Methods: Models that assign exponentially decreasing weights to past observations.

Prophet: An additive regression model that captures trend, seasonality, and holiday effects.

Vector Autoregression (VAR): A multivariate time series model that captures the relationships between variables.

### Time Series Forecasting Cheat Sheet (cont)

#### Machine Learning for Time Series

Regression Models: Linear regression, random forest, support vector machines (SVM), or gradient boosting algorithms can be used with appropriate feature engineering.

#### Long Short-Term Memory (LSTM)

Networks: A type of recurrent neural network (RNN) suitable for modeling sequential data.

Convolutional Neural Networks (CNN): Can be applied to time series data by treating the series as an image.

#### Feature Engineering

Lagged Variables: Include lagged versions of the target variable or other relevant variables as features.

Rolling Statistics: Compute rolling mean, standard deviation, or other statistics over a window of observations.

Seasonal Features: Extract features representing day of the week, month, or other seasonal patterns.

Fourier Transform: Convert time series data to frequency domain to identify periodic components.

#### Validation and Evaluation Metrics

Train-Validation-Test Split: Split the time series into training, validation, and test sets.

Evaluation Metrics: Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), Mean Absolute Percentage Error (MAPE), and symmetric MAPE (sMAPE) are commonly used.

#### Cross-Validation for Time Series

### Time Series Forecasting Cheat Sheet (cont)

Time Series Cross-Validation: Use rolling window or expanding window techniques to simulate the real-time forecasting scenario.

#### Ensemble Methods

Combine forecasts from multiple models or model configurations to improve accuracy and robustness.

Examples include model averaging, weighted averaging, and stacking

#### Outliers and Anomalies

Identify and handle outliers and anomalies to prevent their influence on the forecasting process.

Techniques include moving averages, median filtering, or statistical tests.

#### Handling Missing Data

Imputation Techniques: Use interpolation, mean imputation, or model-based imputation to fill missing values.

### Hyperparameter Tuning Cheat Sheet

#### What are Hyperparameters?

Hyperparameters are configuration settings that are not learned from the data but are set before the training process.

They control the behavior and performance of machine learning models.

#### Hyperparameter Tuning Techniques:

### Hyperparameter Tuning Cheat Sheet (cont)

Grid Search: Exhaustively searches all possible combinations of hyperparameters within predefined ranges.

Random Search: Randomly samples hyperparameters from predefined ranges, allowing more efficient exploration.

Bayesian Optimization: Uses prior knowledge and statistical methods to intelligently search the hyperparameter space.

Genetic Algorithms: Mimics natural selection to evolve a population of hyperparameter configurations over multiple iterations.

#### Automated Hyperparameter Tuning

Libraries: Tools like Optuna, Hyperopt, or scikit-learn's GridSearchCV and RandomizedSearchCV can automate the hyperparameter tuning process.

#### Hyperparameters to Consider

### Hyperparameter Tuning Cheat Sheet (cont)

**Learning Rate:** Controls the step size during model training.

**Number of Hidden Units/Layers:** Determines the complexity and capacity of neural networks.

**Regularization Parameters:** Control the trade-off between model complexity and overfitting.

**Batch Size:** Determines the number of samples processed before updating model weights.

**Dropout Rate:** Probability of dropping out units during training to prevent overfitting.

**Activation Functions:** Choices like sigmoid, tanh, ReLU, or Leaky ReLU impact the model's non-linearity.

**Optimizer:** Algorithms like stochastic gradient descent (SGD), Adam, or RMSprop that update model weights during training.

**Number of Trees and Tree Depth:** Parameters for ensemble methods like Random Forest or Gradient Boosting models.

**Kernel Type and Parameters:** For models like Support Vector Machines (SVM) that use kernel functions.

#### Define Hyperparameter Ranges

Establish reasonable ranges for each hyperparameter based on prior knowledge, literature, or experimentation.

Consider the scale and distribution of values (linear, logarithmic) that make sense for each hyperparameter.

#### Sequential vs. Parallel Tuning

### Hyperparameter Tuning Cheat Sheet (cont)

**Sequential tuning** explores hyperparameter combinations one by one, allowing feedback from each trial to inform the next.

**Parallel tuning** performs multiple hyperparameter evaluations simultaneously, making efficient use of computational resources.

#### Evaluate and Compare Models

Define an evaluation metric (e.g., accuracy, F1-score, mean squared error) that reflects the performance of interest.

Keep a record of the performance for each hyperparameter configuration to compare the models later.

#### Cross-Validation

Use techniques like k-fold cross-validation to estimate the generalization performance of different hyperparameter configurations.

Avoid tuning hyperparameters on the test set to prevent overfitting and biased performance estimation.

#### Early Stopping

Monitor a validation metric during training and stop the training process early if performance deteriorates consistently.

Prevents overfitting and saves computational resources.

#### Feature Selection and Dimensionality Reduction

Consider using techniques like feature selection or dimensionality reduction algorithms (e.g., PCA) as part of hyperparameter tuning.

They can influence model performance and help improve efficiency.

#### Domain Knowledge

### Hyperparameter Tuning Cheat Sheet (cont)

Leverage domain knowledge to guide the selection of hyperparameters.

Prior knowledge can help narrow down the search space and focus on hyperparameters likely to have a significant impact.

#### Regularize Hyperparameters

Apply regularization techniques like L1 or L2 regularization to hyperparameters.

Regularization helps control the complexity and prevent overfitting of the models.

#### Documentation and Reproducibility

Keep a record of the hyperparameter configurations, evaluation metrics, and other relevant details for reproducibility.

Document the lessons learned and insights gained during the hyperparameter tuning process.

### Model Evaluation and Metrics Cheat Sheet

#### Confusion Matrix

A table that summarizes the performance of a classification model.

It shows the counts of true positives, true negatives, false positives, and false negatives.

#### Accuracy

The proportion of correct predictions over the total number of predictions.

Accuracy =  $(TP + TN) / (TP + TN + FP + FN)$

#### Precision

The proportion of true positive predictions over the total number of positive predictions.

Precision =  $TP / (TP + FP)$

Recall (Sensitivity or True Positive Rate)

### Model Evaluation and Metrics Cheat Sheet (cont)

The proportion of true positive predictions over the total number of actual positives.

$$\text{Recall} = TP / (TP + FN)$$

#### Specificity (True Negative Rate)

The proportion of true negative predictions over the total number of actual negatives.

$$\text{Specificity} = TN / (TN + FP)$$

#### F1-Score

The harmonic mean of precision and recall.

$$\text{F1-Score} = 2 (\text{Precision} \text{ Recall}) / (\text{Precision} + \text{Recall})$$

#### Receiver Operating Characteristic (ROC) Curve

A plot of the true positive rate (sensitivity) against the false positive rate (1 - specificity) at various classification thresholds.

It illustrates the trade-off between sensitivity and specificity.

#### Area Under the ROC Curve (AUC-ROC)

A measure of the overall performance of a binary classification model.

AUC-ROC ranges from 0 to 1, with higher values indicating better performance.

#### Mean Squared Error (MSE)

The average of the squared differences between predicted and actual values.

$$\text{MSE} = (1/n) * \sum (y_{\text{pred}} - y_{\text{actual}})^2$$

#### Root Mean Squared Error (RMSE)

The square root of the mean squared error.

$$\text{RMSE} = \sqrt{\text{MSE}}$$

#### Mean Absolute Error (MAE)

### Model Evaluation and Metrics Cheat Sheet (cont)

The average of the absolute differences between predicted and actual values.

$$\text{MAE} = (1/n) * \sum |y_{\text{pred}} - y_{\text{actual}}|$$

#### R-squared (Coefficient of Determination)

A measure of how well the regression model fits the data.

R-squared ranges from 0 to 1, with higher values indicating a better fit.

#### Mean Average Percentage Error (MAPE)

The average percentage difference between predicted and actual values.

$$\text{MAPE} = (1/n) \sum (|y_{\text{pred}} - y_{\text{actual}}| / y_{\text{actual}}) 100$$

#### Cross-Validation

A technique to assess the performance of a model on unseen data by splitting the data into multiple folds.

It helps estimate the model's generalization performance and mitigate issues like overfitting.

#### Bias-Variance Trade-off

Bias refers to the error introduced by approximating a real-world problem with a simplified model.

Variance refers to the model's sensitivity to fluctuations in the training data.

Balancing bias and variance is crucial for building models that generalize well.

#### Overfitting and Underfitting

### Model Evaluation and Metrics Cheat Sheet (cont)

Overfitting occurs when a model performs well on training data but poorly on unseen data.

Underfitting occurs when a model is too simple to capture the underlying patterns in the data.

Regularization techniques and proper model complexity selection can help address these issues.

#### Feature Importance

Techniques like feature importance scores, permutation importance, or SHAP values help identify the most influential features in a model.

#### Model Selection

Compare and select models based on evaluation metrics, cross-validation results, and domain-specific considerations.

Avoid selecting models solely based on a single metric without considering the context.
