

Registers	Flag Registers (cont)	Memory Registers (cont)	Addressing Modes
<p>A (Accumulator)</p> <p>After performing arithmetical or logical operations, the result is stored here</p>	<p>Z (Zero Flag)</p> <p>If an operation performed in A results 0 value of entire 8-bits then zero flag is set, else it resets.</p>	<p>PSW (Program Status Word)</p> <p>It combines the Accumulator register with all the flag registers in a 16-bit format</p>	<p>Direct Addressing</p> <p>In this addressing mode, the address of the operand (data) is given in the instruction itself.</p>
<p>BC</p> <p>General-purpose register that is capable of storing 16-bit data (B - 8-bit) (C - 8-bit)</p>	<p>AC (Auxiliary Carry Flag)</p> <p>If an operation performed in A generates the carry from lower nibble (D0 to D3) to upper nibble (D4 to D7) AC flag is set, else it resets.</p>	<p>Note: A stack is nothing but a portion of RAM (Random access memory).</p> <p>Each time when the data is loaded into stack, Stack pointer gets decremented. Conversely it is incremented when data is retrieved from stack.</p> <p>A stack is treated as a 16-bit entry and it consumes 2 locations from a memory for 1 entry.</p> <p>A stack requires a 16-bit register to be pointed to.</p>	<p>Register Addressing</p> <p>In register addressing mode, the operand is in one of the general purpose registers. The opcode specifies the address of the register(s) in addition to the operation to be performed.</p>
<p>DE</p> <p>General-purpose register that is capable of storing 16-bit data (D - 8-bit) (E - 8-bit)</p>	<p>P (Parity Flag)</p> <p>If the result contains even no. of ones this flag is set and for odd no. of ones this flag is reset.</p>	<p>Machine Cycles</p> <p>Opcode Fetch Machine Cycle 4T or 6T</p> <p>Memory Read Machine Cycle 3T</p> <p>Memory Write Machine Cycle 3T</p> <p>I/O Read Machine Cycle 3T</p> <p>I/O Write Machine Cycle 3T</p> <p>Most of the time, it's just 4T for the Opcode Fetch, there are only a few commands that require 6T</p>	<p>Register Indirect Addressing</p> <p>In Register Indirect mode of addressing, the address of the operand is specified by a register pair.</p>
<p>HL</p> <p>Usually used to store a memory address Ex. (00 - H) (36 - L). It also creates a hypothetical register labeled as 'M'</p>	<p>CY (Carry Flag)</p> <p>If an operation performed in A generates the carry from D7 to next stage then CY flag is set, else it is reset.</p>		<p>Immediate Addressing</p> <p>In this addressing mode, the operand is specified within the instruction itself.</p>
<p>Note: The general purpose registers in 8085 processors are B, C, D, E, H and L.</p> <p>Each register can hold 8-bit data.</p> <p>They can work in pairs such as B-C, D-E and H-L to store 16-bit data.</p> <p>The H-L pair works as a memory pointer.</p>	<p>Note – The Auxiliary Carry flag register in 8085 is the only flag not accessible by the user.</p>		<p>Implicit Addressing</p> <p>There are certain instructions which operate on the content of the accumulator. Such instructions do not require the address of the operand.</p>
<p>Flag Registers</p> <p>S (Sign Flag)</p> <p>If MSB bit = 0 then the number is positive, else it is negative.</p>	<p>Memory Registers</p> <p>PC (Program Counter)</p> <p>Stores the address of the next instruction to be executed.</p> <p>SP (Stack Pointer)</p> <p>Stack pointer maintains the address of the last byte that is entered into stack.</p>		<p>Examples:</p> <ol style="list-style-type: none"> Direct Addressing: STA 2400H Register Addressing: MOV A, B Register Indirect Addressing LXI H, 2500 H MOV A, M Immediate Addressing LXI H, 2500 Implicit Addressing CMA, RAL, RAR, etc.
