Entity-relationship model

An **entity** is a thing that exists either physically or logically. Entities can be thought of as nouns: *a company*, *a computer*.

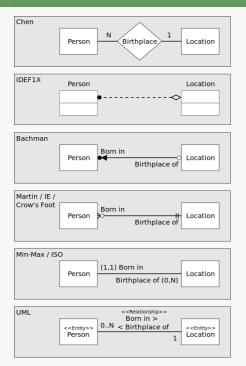

A **relationship** captures how entities are related to one another.

Relationships can be thought of as verbs, linking two or more nouns.

Entities and relationships can both have attributes.

Every entity must have a minimal set of uniquely identifying attributes, which is called the entity's **primary key**.

Relation representation

Various methods of representing the same one to many relationship. In each case, the diagram shows the relationship between a person and a place of birth: each person must have been born at one, and only one, location, but each location may have had zero or more people born at it.

Entity-relationship models

Class diagram

Data modeling

Use case

UML diagrams

class diagram	a type of static structure diagram that describes the structure of a system by showing the system's classes, their attributes, operations, and the relationships among objects.
	objects.
object diagramm	shows a complete or partial view of the system at a given moment of time

conceptual model of the domain that incorporates both:

Class diagramm

domain

model

BankAccount

owner: String
balance: Dollars = 0

deposit (amount: Dollars)
withdrawal (amount: Dollars)

Three compartments of class diagramm:

behaviour and data

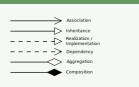

- Name of the class;
- Attributes of the class;
- Methods of the class;

Class members visibility

+	public
-	private
#	protected
1	derived
~	package

To specify the visibility of a class member (i.e. any attribute or method), these notations must be placed before the member's name

UML relations notation

Instance-level relationships in class diagramms

connection between dependent and independent dependency

> model elements; exists when changes to one element may cause changes in dependent element; this

relation in uni-directional

association association is a relationship between two classes

when, that allows one instance to perform an action

on behalf of another;

aggregation is a variant of "has a" relationship; it can aggregation

> occur when a class is a collection of other classes; contained classes are not automatically destroyed

when the container is

more specific version of aggregation; when container composition

> destroyed every insance if contains will be destroyed as well; composition unlike aggregation is a "whole--

part" relationship

Both aggregation and composition are types of association betweetn classes. The aggregation relationship is often "catalog" containment to distinguish it from composition's "physical" containment.

Class-level relationship

indicates that subcless is a cperialized form of superclass; inheri-

implements "is a" relationship; tance

realizrelationship between compotent and it's interface;

ation

General relationship

dependency

weaker form of bond that indicates that one class is dependent on the other; one class depends on another when the independent class is a paramter or local variable;
