Search Methods		
Tree Search	Expand nodes using gradients	
Graph Search	Avoids revisiting nodes and ensure efficiency	

Graph Search	Avoids revisiting nodes and ensure efficiency	
Uninformed sea	rch	
Uniform cost search	aka Cheapest-first Add visited node to Explored and add its neighbors to the frontier Visit cheapest node in the frontier Move to next cheapest if all neighbors are explored	
Iterative deepening	Iteratively calls depth-limited search Initialize frontier with root If not goal, remove from frontier and expand If at the end of depth, terminate and start over Repeat until goal is found Guaranteed to find optimal path More efficient than DFS Time complexity: O(b^d) Space complexity: O(d)	
Bidirectional	Finds shortest path of a grpah	

Informed Search	
Best-first search	Choose unvisited node with the best heuristic value to visit next Same as lowest cost BFS
Greedy best-first search	Uses heuristic to get the node closest to the goal Bad performance if heuristic is bad Does NOT consider cost of getting to the node

Informed Search (cont)		
A* search	Always expand to node with minimum f Evaluate cost of getting to goal using heuristics f(n) = g(n)+h(n) where g is cost to get to n Uses priority queue	
Heuristics	Cost to get to the goal	
Admissible herustic	Optimistic model for estimating cost to reach the goal Never overestimates $h(n) \le c(n)$ where c is actual cost	
Consistent heuristic	$h(n) \le c(n, a, n') + h(n')$ Immediate path costs less than longer path Consistent \Longrightarrow Admissible	

neuristic	Consistent → Admissible	
Consistent h	neuristic	
	Consistent heuristics • A heuristic is consistent if for every node n , every successor n of n generated by any action a , $h(n) \leq c(n,a,n') + h(n')$ • If h is consistent, we have $f(n') = g(n') + h(n)$ $\geq g(n) + h(n)$ $\geq g(n) + h(n)$ $\geq g(n) + h(n)$ $= f(n)$ • i.e., $f(n)$ is non-decreasing along any path. Theorem: If $h(n)$ is consistent, A* using GRAPH-SEARCH is optimal	

Adversarial Search		
Hill climbing	Method of local search Only move to neighbors to find the max Does NOT guarantee to find optimal	
Simulated annealing	Method of local search Combine hill climbing and random walk Always find global max

Adversarial Search (cont) Local beam Generate k random states Generate successors of all k states If goal stop; else, pick k best successors and repeat Different from hill-climbing since information is shared between k points Genetic Cross-Over and mutation algorithm Decomposes strands of DNA and permute

Produces children by: Selection, Cross-over, Mutation

Propositional SAT: Graph coloring	
At lest 1 of K per i	(Ci,1 v Ci,2 v v Ci,k) O(n) clauses
1 ≥ color per i	∀ k≠k' (¬Ci,k ∨ ¬Ci,k') O(n^2)
If node i and j share an edge	$\forall \ x{\in}k, \ (\neg Ci, x \lor \neg Cj, \ x)$

function alphabeta (node, depth, α , β , maximizingPlayer) if depth = or node is a terminal node return the heuristic value of node if maximi zin gPlayer ∨ := -∞ for each child of node v := max(v, alphab eta (child, depth - 1, α , β , FALSE)) $\alpha := \max(\alpha, v)$ if $\beta \leq \alpha$ β cutbo€£k)(return v else ∨ := ∞ for each child of node v := min(v, alphab eta (child,depth - 1, α , β , TRUE)) $\beta := \min(\beta, v)$ if $\beta \leq \alpha$ α cutbo€£k)(

α-β Pruning

return v
