

COMP160 Cheat Sheet

by exo via cheatography.com/19823/cs/2776/

Lecture 14 - References

- * Reference types include String, Array and other classes.
- * This is a keyword that always refers to the current instance object.
- * No need for different parameter names.

Lecture 16 - Arrays 2

- * The state of an array can be changed by a reference to an array (a change to the reference b for listener example will also change a)
- AClass [] $z = \{\text{new AClass}(), \text{new AClass}^{9}\} (\frac{1}{3}; 3, " \text{hel lo"}, 3), \text{new AClass}()$

- * Objects that represent events in the GUI (button clicks, mosue clicks, text input etc.)
- * Remember to import java.awt.*; javax.swing.*; java.awt.event.*;
- * Event model: (event generator object makes an) Programmer creates components and registers listener for each one. (even object reference sent to) automatically handlered whe user generates an event. (event listener object) programmer creates listener objects

- * Extends: we can extend a class to create/define a new class (subclass/child) A child class has it own member (datafields & members) and also non private members of the parent class.
- * Hierarchy: A class inherits from its parent, this is how objects get methods like toString that aren't its own
- * Super: keyword refering to members of current class/object inherited from the parent class

Lecture 24 - Collections, ArrayList, Applets

- * Enumerated Types: Enumerated types are a wayt of core at ing a new row : b) { type by enumerating (listing) every possible value. for (double x : row) {
- * Generics: where programs are written in terms of "to be specifieds tem.ou t.p rint(x
- * Collections: Java has many ways of representing and processing collections of objects, using classes and interfaces in java util These t.p rin tln(); are called collection classes, collection framework, or collection API.

* Arrays are objects and can hold references to objects.

Doesn't hold primitive types.

al.add ("re d");

```
al.add ("gr een ");
String a = al.get(1);
system.ou t.p rin tln(a);
a.inde xOf ("ye llo w");
```

* An array of classes can be made just as if you were creating an array of primative values: (ActionEvent event) {

```
if (event.ge tSo urce() ==
        lab el.s et Text( " -
Lef t");
   else
       lab el.s et Text( " -
```

- * An array is a named collection of data of same type and a fixed size.
- * Index can only be an int (or a char cast to an int)
- * Hold primitive types, references / handles / pointersagekages: A package is a related group of
- * Initialiser lists: int []intAr = { 3, 7, 9, pagkage get put into the default package.
-] [5]; initializing = double [][]b = { $\{1.0^{any}_{,,}3^{class}\}$ extending this one }, {5.6, 8.9} };

Lecture 22 - Visibility, overriding

Rig ht");

- classes. Ones that you don't put into a
- * Visibility package visibility is used when * An array always starts at position 0 and goes to lengifibility is specified - accessible only to classes in this package. protected visibility -* Multidimensional Arrays - int [][]a = new incessible to classes in this package and
 - * Method overloading: A class can have multiple methods of the same name as long as they have different parameter specifications.
 - * Method Overriding: methods with same signature (name and parameter specification) exist in both parent and child class.
 - * When datafields have the same name it is called shadowing

ArrayL ist()

Constructor: creates an initially empty list void add (Object obj)

Inserts the specified object to the end of this

Cheatography

COMP160 Cheat Sheet

by exo via cheatography.com/19823/cs/2776/

ArrayList (cont)

void add(int index, Object object)
Inserts the specified element at the specified
position in this list

void clear()

removes all of the elements from this list Object remove (int index)

Removes the element at the specified position in this list

Object get (int index)

Returns the element at the specified position in this list

int indexO f(O bject obj)

Returns the index of the first occurrence of the specified element in this list,

or -1 if this list does not contain the element boolean contains (Object obj)

Returns true if this list contains the specified element

boolean isEmpty

Returns true if this list contains no elements int size()

Returns the number of elements in this list

Printing out a 2D array

```
for(int row = 0; row < b.length;
row++) {
    for(int col = 0; col <
    b[row].le ngth; col++) {
        Sys tem.ou t.p rint(
    b[row] [col ] + " ");
    }
System.ou t.p rin tln();
}</pre>
```

Lecture 17 - Graphics components

- * Components: Objects that are drawn in the GUI (including containers such as frames and panels).
- * A Container is a type of component that holds and organises other components JPanel holds other components, JFrame holds JPanels in a window

Lecture 17 - Graphics components (cont)

*Layout: (default) FlowLayout: Left to right top to bottom. BorderLayout: 5 positions, north south east west centre. BoxLayout: Single row or column. GridLayout: a grid. Example: add (b5.Bo rde rLa you t.E ast)

*

Lecture 20 - Input/Output

- * A stream is a source or destination of a sequence of data.
- * Tokens are text items separated by "white space"
- * try..catch: exception handling. when error occurs: do nothing program will crash, handle the error with try catch.
- * Use a scanner to read from a file.

Lecture 23 - Abstract classes

- * instanceof (boolean): returns true if an object is an instance of a class i.e. s intanceof Square
- * Abstract Classes: They are used when you want to create instances of subclasses but not the abstract parent itself. Abstract class can have its own normal methods.
- * Abstract methods must be implemented in child classes, have no body in parent class.
- * A child class can only have one parent. Multiple inheritance.
- * Java has interfaces to avoid full multiple inheritance. Interfaces may only contain abstract methods and static final data fields.
- * Final: a final class may not be extended, a final method may not be over ridden.
