

### Major Formulas

<b>Cellular Respiration</b>	$C_6H_{12}O_6 + O_2 \rightarrow H_2O + CO_2$
<b>Photosynthesis</b>	$H_2O + CO_2 \rightarrow C_6H_{12}O_6 + O_2$

### Other

#### (NADH, FADH<sub>2</sub>, NADPH):

Carry e<sup>-</sup> in the form of H<sup>+</sup> ions. They drop e<sup>-</sup> either at the ETC to make ATP or the Calvin Cycle to help bond formation.

#### ATP Synthase:

Enzyme that synthesizes ATP - Uses chemiosmosis in order to in order to phosphorylate ADP into ATP

### ATP Synthase

ATP Synthase transports a proton down the gradient and uses the energy to complete the phosphorylation of ADP to ATP.

### Phosphorylation

### ETC

- 1. Redox of NADH+H<sup>+</sup> at Complex I, electrons go to Complex I, four protons pumped from matrix to intermembrane space**
- 2. Redox of FADH<sub>2</sub> at Complex II, Coenzyme Q picks up electrons (from Complex I and II) and transports to Complex III**
- 3. Redox of Complex III, four protons pumped from matrix to intermembrane space, carrier C transports electrons to Complex IV**
- 4. Redox of Complex IV, two protons pumped from matrix to intermembrane space, formation of H<sub>2</sub>O (20% of water in body)**
- 5. ATP Synthase action, pumps protons from intermembrane space to matrix, produces ATP from ADP + P<sub>i</sub> + energy**

#### Oxygen = Final e<sup>-</sup> Acceptor.

- Step 1: Generating a Proton Motive Force.  
 Step 2: ATP Synthesis via Chemiosmosis.  
 Step 3: Reduction of Oxygen.  
 Summary: Oxidative Phosphorylation.

### Fermentation

<b>Facultative Anaerobes</b>	Tolerate, but do not use, O <sub>2</sub>
<b>Obligate Anaerobes</b>	Cannot live in an environment w/O <sub>2</sub>
<b>Alcoholic Fermentation</b>	Converts pyruvate into ethyl alcohol + CO <sub>2</sub> & oxidizes NADH to NAD <sup>+</sup>
<b>Lactic Acid Fermentation</b>	Reduces pyruvate into lactic acid (lactate) & oxidizes NADH to NAD <sup>+</sup>

### Photosynthesis

### Light Dependent Stage

#### Key Points

- In light-dependent reactions, the energy from sunlight is absorbed by chlorophyll and converted into chemical energy in the form of electron carrier molecules like ATP and NADPH.
- Light energy is harnessed in Photosystems I and II, both of which are present in the thylakoid membranes of chloroplasts.

### Chemiosmosis

#### Chemiosmosis

- The movement of ions across a semipermeable membrane, down their electrochemical gradient. An example of this would be the generation of adenosine triphosphate (ATP) by the movement of hydrogen ions (H<sup>+</sup>) across a membrane during cellular respiration or photosynthesis.

### Photorespiration, C-4, & CAM

<b>Photoresp.</b>	rubisco binds with O <sub>2</sub> instead of CO <sub>2</sub> ; produces no ATP or sugar
<b>C-4 Plants</b>	Use alternate C-fixation (PEP carboxylase) that ends in a 4C compound (occurs in mesophyll & bundle sheath cells)
<b>CAM Plants</b>	Carbon fixation to organic acids at night → light reactions release CO <sub>2</sub> in the day

## Phosphorylation

### I- Substrate-level phosphorylation:

- Some ATP is generated in glycolysis and in Krebs cycle by Substrate-level phosphorylation. Phosphate group is transferred from an organic molecule (the substrate) to ADP, forming 10% ATP (4 ATP).

### II- Oxidative phosphorylation:

- As electrons passed along the chain, their energy stored in the mitochondrion in a form that can be used to synthesize the rest 90% of the ATP (34 ATP).
- via Oxidative phosphorylation.

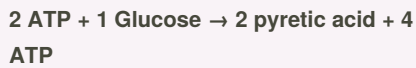

Ultimately 38 ATP are produced per mole of glucose that is degraded to carbon  $\text{CO}_2$  and  $\text{H}_2\text{O}$  by respiration.

## Calvin Cycle / Light Independent Stage

### Key Points

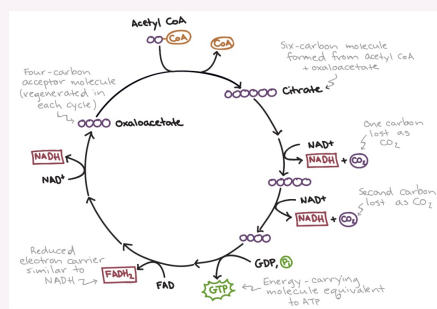

- Carbohydrate molecules are assembled from carbon dioxide using the chemical energy harvested during the light-dependent reactions.

## Glycolysis

PFK = allosteric enzyme inhibited by ATP

## Krebs/Citric Acid Cycle

**Substrate Level Phosphorylation:** ATP + pyruvate

**Pyruvate + coenzyme A:** acetyl CoA

**Products:** 3 NADH, 1 ATP, 1 FADH,  $\text{CO}_2$
