

What is an Oedema?

A shift of plasma to interstitial fluid

An oedema is an accumulation of fluid in the interstitial space

Occurs if venous hydrostatic pressure rises, plasma oncotic pressure decreases or interstitial oncotic pressure rises

May also develop if an obstruction of lymphatic outflow causes decreased removal of interstitial fluid

Lymphedema

Oedema caused by heart failure

Oedema causes

Extracellular fluid volume excess caused by addition or retention of saline (saline overload)

Leaky cap bed

Obstruction to lymph flow

Plasma oncotic pressure decreases

Interstitial oncotic pressure rises

Increase in intravascular hydrostatic pressure/if venous hydrostatic pressure

Associated with cardiac, hepatic, or renal failure & venous insufficiency

Assessing oedema

Where is the oedema? Localised or Generalised?

Localised

Related to trauma or inflammation.

Other examples of localised oedema:
Cerebral, pulmonary, pleural effusion, pericardial effusion, and ascites

Generalised

More uniform distribution of fluid in interstitial spaces

How long has the patient had oedema?

Chronic oedema

Longer than 3 months

What could be the cause?

How does this affect the patient?

Fluid shifts in heart failure

Venous obstruction

Measuring oedema

Dependent oedema: Pitting and non-pitting

Grading oedema

- 1+ Slight pitting/2mm, disappears rapidly
- 2+ Deeper pit/4mm, disappears in 10-15s
- 3+
- 4+ Very deep pit/8mm. lasts 2-5m, extremely grossly distorted

Nursing interventions

Ensure underlying cause is being managed appropriately, attempting to reverse

Position patient to reduce positional fluid collection

Recording measurements of pitting oedema

Daily weigh

Administering diuretics if prescribed

Protecting affected tissue from further injury

What is the pathophysiological rationale?

Effects of oedema: determined by location

Fluid leaves bloodstream and accumulates in interstitial spaces

Circulating blood volume and blood pressure decline

Tissue more susceptible to injury

Poor supply of nutrients and oxygen to support healthy tissue

Up to 50% of patients suffering from oedema experience leg ulceration, with 31% of these people having the ulcer for more than 5 years

Fluid spacing

First spacing

Second spacing Abnormal accumulation of fluid in interstitial spaces, such as oedema. This abnormal accumulation can still be easily moved back to ICF/ECF, where it should be

Third spacing Abnormal accumulation of fluid trapped in spaces where it is difficult or impossible to return to where it should be, such as ascites or burn related injuries. This requires medical intervention to reverse.
