

### Pointers

Storing, data type of pointers and variables must be the same

`&var` Returns address of memory location of variable

`data_type` Initialize. Put \* in front of name

`*pointer;`

`*pointer` Returns value at the memory location stored by pointer

Array variables are actually pointers to the first element in the array. The amount that your pointer moves from an arithmetic operation

`*array` Returns first element in array

`*(array+2)` Returns third element in array

- Variables that you declare are stored in a memory location in your computer

- The address of these memory locations can be stored in pointers

- Addresses are in hexadecimal

### Iterators

```
//Append ::iterator to your data type declaration
to create an iterator of
that data type
```

```
vector<int>::iterator it; // declares an
iterator of vector<int>
```

```
// loops from the start to end of vi
for(decltype vi)::iterator it = vi.begin(); it
!= vi.end(); it++)
```

```
cout << *it << " "; // outputs 1 2 3 4
```

```
deque<int> d;
```

```
deque<int>::iterator it;
```

```
it = d.begin(); //Points to first element
```

```
it++; // Points to next element
```

```
it = d.end(); // Points to Last element
```

```
it--; // Points to previous element
```

```
cout << *it; // outputs the element it is pointing
```

Iterators are essentially pointers to an STL data structure

### Maps

```
map<string, int> M;
```

```
M["hello"] = 2;
```

```
M["asd"] = 986;
```

```
M.count("asd"); // returns 1
```

```
M.count("does not exist"); // returns 0
```

```
M.size();
```

```
// Check for the existence of some key in the map -
O(log N)
```

```
it = M.find("asd"); //returns the iterator to
"asd"
```

```
it = M.upper_bound("aa");
```

```
it = M.lower_bound("aa");
```

```
if (it == M.end())
```

```
cout << "Does not exist \n";
```

```
//Iteration
```

```
for (auto it = mp.begin(); it != mp.end(); ++it)
```

```
{
```

```
cout << it.first << ", " << it.second <<
```

```
"\n";
```

```
}
```

A data structure that takes in any data[key]

Gives you the associated value stored through  $O(\log N)$  magic

Best used when you need to lookup certain values in  $O(\log N)$  time that are associated with other values

### Queue

```
queue<int> q;
```

```
q.push(5); // Inserts/ Enqueue element at the back
of the queue
```

```
q.front(); // Returns element at the front of the
queue
```

```
q.pop // Removes (Dequeues) element from the front
of the queue
```

```
q.empty(); // Returns boolean value of whether
queue is empty
```

First In First Out data structure where elements can only be added to the back and accessed at the front

### Priority Queue

```
priority_queue<data_type> pq; // Largest at top
priority_queue<data_type, vector<data_type>, greater<data_type>> >
pq; // Smallest at top
pq.push(5); // pushes element into it. Duplicates
are allowed
pq.top() // Returns largest or smallest element
pq.pop() // Removes largest or smallest element
pq.size(); // Returns size
pq.empty(); // Check if queue is empty
```

Like a queue except that only the element with the greatest priority (eg. largest/smallest) can be accessed

### Fenwick tree

```
//Below here can mix & match
long long ft[100001]; // note: this fenwick tree
is 1-indexed.
////PU -
PQ/ /// /// /// /// /// /// /// /// /// /// ///
/ /// /// /// ///
void fenwick_update(int pos, long long value) {
    while (pos <= N) {
        //cout <<"Fenwick Updating: " <<
pos <<" "<<endl;
        ft[pos] += value;
        pos += pos & -pos;
    }
}
long long fenwick_query(int pos) {
    long long sum = 0;
    while (pos) { // while p > 0
        sum += ft[pos];
        pos -= pos & -pos;
    }
    return sum;
}
////RU -
PQ/ /// /// /// /// /// /// /// /// /// ///
/ /// /// /// ///
```

### Fenwick tree (cont)

```
> void fenwick_range_update(int pos_a, int pos_b, int val){
    //TLE way
    //for (int i=pos_a;i<=pos_b;i++){fenwick_update(i, val);}
    fenwick_update(pos_a, val);
    fenwick_update(pos_b+1, -val);
}
////PURQ////////////////////////////////////
long long fenwick_range_query(int pos_a, int pos_b) {
    return fenwick_query(pos_b) - fenwick_query(pos_a-1);
}
////RURQ////////////////////////////////////
long long B1[100001];long long B2[100001];
void base_update(long long *ft, int pos, long long value){
    //Add largest power of 2 dividing x / Last set bit in number x
    for (; pos <= N; pos += pos & (-pos))
        ft[pos] += value;
}
void rurq_range_update(int a, int b, long long v){
    base_update(B1, a, v);
    base_update(B1, b + 1, -v);
    base_update(B2, a, v * (a-1));
    base_update(B2, b + 1, -v * b);
}
void rurq_point_update(int a, long long v){
    rurq_range_update(a,a,v);
}
long long base_query(long long *ft,int b){
    long long sum = 0;
    for(; b > 0; b -= b & (-b))
        sum += ft[b];
}
```

### Fenwick tree (cont)

```
> return sum;
}
// Return sum A[1...b]
long long rurq_query(int b){
    return base_query(B1, b) * b - base_query(B2, b);
}
//Return sum A[a...b]
long long rurq_range_query(int a,int b){
    return rurq_query(b) - rurq_query(a-1);
}
```

### Pair

```
// Initialise
pair<data_type_1, data_type_2> variable;
// OR
pair<data_type_1, data_type_2> variable =
make_pair (value 1,value2);
// Store values
variable.first = value;
variable.second = value;
// Retrieve values
cout <<variable.first << " " << variable.second
<< endl;
//Nesting pairs
pair<int, pair<int, int> > a;
a.first = 5;
a.second.first = 6;
a.second.second = 7;
```

Stores a pair of values

### Stack

```
stack<int> s;
s.push(5); // push an element onto the stack -
O(1)
s.pop(); // pop an element from the stack - O(1)
s.top(); // access the element at the top of the
stack - O(1)
s.empty(); // whether stack is empty - O(1)
```

First-In-Last-Out data structure

Only Element at the top can be accessed / removed

### Vector

```
// Initialize
vector<data_type> v;
v.push_back( value); // Add element to back
v.pop_back() // Remove last element
v.clear(); // Remove all elements
v[index] // Return element of index
v.back(); // Return last element
v.size(); // Return Size of vector
v.empty() // Return boolean value of whether
vector is empty
```

Like arrays but re-sizable. You can add and remove any number of elements from any position.

### Sets and Multisets

```
set<int> s; set<int>::iterator it;
multiset< int> s; multiset< int >:: iterator it;
s.insert(10);
it = s.find(8)
it = s.upper_bound(7);
it = s.lower_bound(7);
s.erase(10); //Remove element from set
s.erase(it) //Can also use iterators
s.empty();
```

### Sets and Multisets (cont)

```
> s.clear();
// to loop through a set
for(it = s.begin(); it != s.end(); it++)
    cout << *it << " "; // outputs 2 7 10
```

In a set: All elements are sorted and no duplicates  
Multisets can store duplicates though

### Deque

```
deque<int> d;
// access an element / modify an element (0-indexed
as well) - O(1)
d[0] = 2; // change deque from {5, 10} to {2, 10}
d[0]; // returns a value of 2
d.back(); // get back (last) element - O(1)
d.front(); // get front (first) element - O(1)
d.clear() // Remove all elements
d.push_back(5); // add an element to the back -
O(1)
d.push_front(10); // add an element to the front
- O(1)
d.pop_back(); // remove the back (last) element -
O(1)
d.pop_front(); // remove the front (first)
element - O(1)
d.size(); //Return size
d.empty() // Whether queue is empty
```

A stack and queue combined.  
...or a vector that can be pushed and popped from the front as well.

Deque = Double Ended Queue!

### Segment Tree

```
struct node {
    int start, end, mid, val, lazyadd;
    node* left, right;

    node(int _s, int _e) {
        //Range of values stored
        start = _s; end = _e; mid =
        (start + end) / 2;
```

### Segment Tree (cont)

```
> //Min value stored
val = 0; lazyadd = 0;
if (start!=end) {
    left = new node(start,mid);
    right = new node(mid+1,end);
}
}

int value(){
    if (start==end){
        val += lazyadd; lazyadd = 0; return val;
    }else{
        val += lazyadd;
        // Propagate Lazyadd
        right->lazyadd += lazyadd;
        left->lazyadd += lazyadd;
        lazyadd = 0;
        return val;
    }
}

void addRange(int lower_bound, int upper_bound, int val_to_add){
    if (start == lower_bound && end == upper_bound){
        lazyadd += val_to_add;
    }else{
        if (lower_bound > mid){
            right->addRange(lower_bound, upper_bound, val_to_add);
        }else if (upper_bound <= mid){
            left->addRange(lower_bound, upper_bound, val_to_add);
        }else{
            left->addRange(lower_bound, mid, val_to_add);
            right->addRange(mid+1, upper_bound, val_to_add);
        }
    }
}
```

### Segment Tree (cont)

```

>     }
      val = min(left->value(), right->value());
    }
  }

// Update position to new_value // O(log N)
void update(int pos, int new_val) { //position x to new value
  if (start==end) { val=new_val; return; }
  if (pos>mid) right->update(pos, new_val);
  if (pos<=mid) left->update(pos, new_val);
  val = min(left->val, right->val);
}

// Range Minimum Query // O(log N)
int rangeMinimumQuery(int lower_bound, int upper_bound) {
  //cout<<"Node:"<<start<<" "<<end<<" "<<mid<<" "<<val<<endl;
  //If Query Range Corresponds////////////////////
  if (start==lower_bound && end==upper_bound){
    return value();
  }
  //Query Right Tree if range only lies there
  else if (lower_bound > mid){
    return right->rangeMinimumQuery(lower_bound, upper_ -
bound);
  }
  //Query Left Tree if range only lies there
  else if (upper_bound <= mid){
    return left->rangeMinimumQuery(lower_bound, upper_ -
bound);
  }
  //Query both ranges as range spans both trees
  else{
    return min(left->rangeMinimumQuery(lower_bound, mid),r-
ight->rangeMinimumQuery(mid+1, upper_bound));
}

```

### Segment Tree (cont)

```

>     }
      //End////////////////////////////////////
    }

} *root;
void init(int N){
  root = new node(0, N-1); // creates seg tree of size n
}
void update(int P, int V){
  root->update(P,V);
}
int query(int A, int B){
  int val = root->rangeMinimumQuery(A,B);
  return val;
}

```
