## Java Data Structures Cheat Sheet by leternalleo via cheatography.com/45716/cs/13401/

Defi-- Stores data elements based on an nitiosequential, most commonly 0 based, index. - Based on [tuples] n (http://en.wikipedia.org/wiki/Tuple) from set theory. - They are one of the oldest, most commonly used data structures. Detai - Optimal for indexing; bad at searching, inserting, and deleting ls (except at the end). - Linear arrays, or one dimensional arrays, are the most basic. - Are static in size, meaning that they are declared with a fixed size. -Dynamic arrays are like one dimensional arrays, but have reserved space for additional elements. - If a dynamic array is full, it copies it's contents to a larger array. - Two dimensional arrays have x and y indices like a grid or nested arrays. Big-- Indexing: Linear array: O(1), Dynamic

0 array: O(1) - Search: Linear array: O(n), Dynamic array: O(n) - Optimized effici Search: Linear array: O(log n), ency Dynamic array: O(log n) - Insertion: Linear array: n/a Dynamic array: O(n)

### Linked List

Emitou	
Defi- nitio- n	- Stores data with <b>nodes</b> that point to other nodes Nodes, at its most basic it has one datum and one reference (another node) A linked list _chains_ nodes together by pointing one node's reference towards another node.
Detai Is	<ul> <li>Designed to optimize insertion and deletion, slow at indexing and searching Doubly linked list has nodes that reference the previous node Circularly linked list is simple linked list whose tail, the last node, references the head, the first node Stack, commonly implemented with linked lists but can be made from arrays too Stacks are last in, first out (LIFO) data structures Made with a linked list by having the head be the only place for insertion and removal Queues, too can be implemented with a linked list or an array Queues are a first in, first out (FIFO) data structure.</li> <li>Made with a doubly linked list that only removes from head and adds to tail.</li> </ul>
Big- O	- Indexing: Linked Lists: O(n) - Search: Linked Lists: O(n) - Optimized Search:

Linked Lists: O(n) - Insertion: Linked effici Lists: O(1) ency

Defi- nitio- n	- Stores data with key value pairs <b>Hash functions</b> accept a key and return an output unique only to that specific key This is known as <b>hashing</b> , which is the concept that an input and an output have a one-to-one correspondence to map information Hash functions return a unique address in memory for that data.
Detai Is	- Designed to optimize searching, insertion, and deletion <b>Hash</b> <b>collisions</b> are when a hash function returns the same output for two distinct inputs All hash functions have this problem This is often accommodated for by having the hash tables be very large Hashes are important for associative arrays and database indexing.
Big- O effici ency	- Indexing: Hash Tables: O(1) - Search: Hash Tables: O(1) - Insertion: Hash Tables: O(1)

Binar	y Tree
Defi	- Is a tree like data structure where
niti	every node has at most two children
on	There is one left and right child node.

#### Binary Tree (cont)

- Detai - Designed to optimize searching and
- sorting. A degenerate tree is an ls unbalanced tree, which if entirely onesided is a essentially a linked list. -They are comparably simple to implement than other data structures. -Used to make binary search trees. - A binary tree that uses comparable keys to assign which direction a child is. -Left child has a key smaller than it's parent node. - Right child has a key greater than it's parent node. - There can be no duplicate node. - Because of the above it is more likely to be used as a data structure than a binary tree. An AVL Tree is a balanced binary search tree. -The process for inserting or deleting is the same as in a regular(unbalanced) BST, except you have to rebalance after each operation. A node in an AVL tree is balanced if its balance factor is either -1,0, or 1 Big-- Indexing: Binary Search Tree: O(log 0 n) - Search: Binary Search Tree: O(log n) - Insertion: Binary Search Tree: effici O(log n) ency

The balance factor of a node is the height of its right subtree minus the height of its left subtree

#### **Breadth First Search**

Defi-	- An algorithm that searches a tree (or	
nitio-	graph) by searching levels of the tree	
n	first, starting at the root It finds every	

node on the same level, most often moving left to right. - While doing this it tracks the children nodes of the nodes on the current level. - When finished examining a level it moves to the left most node on the next level. - The bottom-right most node is evaluated last (the node that is deepest and is farthest right of it's level).

Detai - Optimal for searching a tree that is wider than it is deep. - Uses a queue to ls store information about the tree while it traverses a tree. - Because it uses a queue it is more memory intensive than depth first search. - The queue uses more memory because it needs to stores pointers

Big-- Search: Breadth First Search: O(|E| + |V|) - E is number of edges - V is 0 number of vertices effici

#### ency

#### Depth First Search

- An algorithm that searches a tree (or Defi niti graph) by searching depth of the tree first, starting at the root. - It traverses left on down a tree until it cannot go further. -Once it reaches the end of a branch it traverses back up trying the right child of nodes on that branch, and if possible left from the right children. - When finished examining a branch it moves to the node right of the root then tries to go left on all it's children until it reaches the bottom. - The right most node is evaluated last (the node that is right of all it's ancestors).

#### Published 6th November, 2017. Last updated 6th November, 2017. Page 2 of 3.

#### Depth First Search (cont)

Detai	- Optimal for searching a tree that is		
ls	deeper than it is wide Uses a stack		
	to push nodes onto Because a stack		
	is LIFO it does not need to keep track		
of the nodes pointers and is therefore			
	less memory intensive than breadth		
	first search Once it cannot go further		
	left it begins evaluating the stack.		
Big-	- Search: Depth First Search: O( E  +		
0	V ) - E is number of edges - V is		

|V|) - E is number of edges - V is number of vertices effici

```
encv
```

### Breadth First Search Vs. Depth First Search

- The simple answer to this question is that it depends on the size and shape of the tree. - For wide, shallow trees use Breadth First Search
- For deep, narrow trees use Depth First Search

#### Nuances:

- Because BFS uses queues to store information about the nodes and its children, it could use more memory than is available on your computer. (But you probably won't have to worry about this.)

- If using a DFS on a tree that is very deep you might go unnecessarily deep in the search. See [xkcd](http://xkcd.com/761/) for more information.

- Breadth First Search tends to be a looping algorithm.

- Depth First Search tends to be a recursive algorithm.

## Merge Sort

Defi-	- A comparison based sorting algorithm			
nitio-	- Divides entire dataset into groups of			
n	at most two Compares each number			
	one at a time, moving the smallest			
	number to left of the pair Once all			
	pairs sorted it then compares left most			
	elements of the two leftmost pairs			
	creating a sorted group of four with the			
	smallest numbers on the left and the			
	largest ones on the right This process			
	is repeated until there is only one set.			
Detai	- This is one of the most basic sorting			
ls	algorithms Know that it divides all the			

ls	algorithms Know that it divides all the
	data into as small possible sets then
	compares them.
Big-	- Best Case Sort: Merge Sort: O(n) -
0	Average Case Sort: Merge Sort: O(n

effici log n) - Worst Case Sort: Merge Sort: ency O(n log n)

### Quicksort

Defi	- A comparison based sorting algorithm -	
niti	Divides entire dataset in half by selecting	
on the average element and putting all		
	smaller elements to the left of the	
average It repeats this process on th		
left side until it is comparing only two		
elements at which point the left side is		
	sorted When the left side is finished	
sorting it performs the same operation		
on the right side Computer		
	architecture favors the quicksort	
	process.	

#### Quicksort (cont

Detai	- While it	has the	same	Big O	as (or
-------	------------	---------	------	-------	--------

Is worse in some cases) many other sorting algorithms it is often faster in practice than many other sorting algorithms, such as merge sort. - Know that it halves the data set by the average continuously until all the information is sorted.

Big- - Best Case Sort: Merge Sort: O(n) -

 O
 Average Case Sort: Merge Sort: O(n

 effici
 log n) - Worst Case Sort: Merge Sort:

 ency
 O(n^2)

#### Bubble Sort

Defi- nitio- n	<ul> <li>A comparison based sorting algorithm</li> <li>It iterates left to right comparing every couplet, moving the smaller element to the left.</li> <li>It repeats this process until it no longer moves and element to the left.</li> </ul>
Detai Is	- While it is very simple to implement, it is the least efficient of these three sorting methods Know that it moves one space to the right comparing two elements at a time and moving the smaller on to left.
Big- O effici ency	- Best Case Sort: Merge Sort: $O(n)$ - Average Case Sort: Merge Sort: $O(n^2)$ - Worst Case Sort: Merge Sort: $O(n_2)$

#### Merge Sort vs. QuickSort

- Quicksort is likely faster in practice.

- Merge Sort divides the set into the smallest possible groups immediately then reconstructs the incrementally as it sorts the groupings.

- Quicksort continually divides the set by the average, until the set is recursively sorted.

#### Heap Sort

Definitio n:	Sorts using a complete binary Tree.
Details:	ArrayList can be used to store a Heap For a node of i: -Left child: 2i+1 -Right child: 2i+2 -Parent: (i - 1)/2
Big-O:	O(nlogn)
