Old (cont)		
Strong Induction: To prove that P(n) is true for all positive integers n, where P(n) is a propositional function, complete two steps: Basis Step: Verify that the proposition P(1) is true. Inductive Step: Show the conditional statement [P(1) ∧ P(2) ∧ ... ∧ P(k)] → P(k + 1) holds for all positive integers k. Ordina-ry/weak induction • Rule 1: P(0) (or any other base case) • Rule 2: P(n) → P(n+1)	Example: Show that if n is an integer greater than 1, then n can be written as the product of primes. Solution: Let P(n) be the proposition that n can be written as a product of primes. BASIS STEP: P(2) is true since 2 itself is prime. INDUCTIVE STEP: The inductive hypothesis is P(j) is true for all integers j with 2 ≤ j ≤ k. To show that P(k + 1) must be true under this assumption, two cases need to be considered: If k + 1 is prime, then P(k + 1) is true. Otherwise, k + 1 is composite and can be written as the product of two positive integers a and b with 2 ≤ a ≤ b < k + 1. By the inductive	Example: Prove that every amount of postage of 12 cents or more can be formed using just 4-cent and 5-cent stamps. Solution: Let P(n) be the proposition that postage of n cents can be formed using 4-cent and 5-cent stamps. BASIS STEP: P(12), P(13), P(14), and P(15) hold. P(12) uses three 4-cent stamps. P(13) uses two 4-cent stamps and one 5-cent stamp. P(14) uses one 4-cent stamp and two 5-cent stamps. P(15) uses three 5-cent stamps. INDUCTIVE STEP: The inductive hypothesis states that P(j) holds for 12 ≤ j ≤ k, where k ≥ 15. Assuming the inductive

Turing Machine		
A Turing machine T = (S, I, f, s0) consists of a finite set S of states, an alphabet I that includes the blank symbol B, a partial function f from (S × I) → (S × I × {R,L}) a starting state s0. For some (state, symbol) pairs the partial function f may be undefined, but for a pair for which it is defined, there is a unique (state, symbol, direction) triple associated to this pair. The five-tuples corresponding to the partial function in the definition of a TM are called the transition rules of	1. At the beginning of its operation a TM is assumed to be in the initial state s0 and to be positioned over the leftmost nonblank symbol on the tape. This is the initial position of the machine. 2. At each step, the control unit reads the current tape symbol x. 3. If the control unit is in state s and if the partial function f is defined for the pair (s, x) with f(s, x) = (s', x', d), the control unit: enters the state s', writes the symbol x' in the current cell, erasing x, and moves right one cell if d = R or moves left one cell if d = L. 4. This step is written as the five-tuple (s, x, s', x', d). Turing machines are defined by specifying a set of such five-tuples. If the partial	Let V be a subset of an alphabet I. A TM T = (S, I, f, s0) recognizes a string x in V if and only if T, starting in the initial position when x is written on the tape, halts in a final state. T is said to recognize a subset A of V if it is the case that a string x is recognized by T if and only if x belongs to A. Note that to recognize a subset A of V* we can use symbols not in V. This means that the input alphabet I may include symbols not in V. We will see that these extra symbols are used as markers. A TM operating on a tape containing the symbols of a string x in consecutive cells,

a and b are positive integers, the gcd(a, b) can be written as $\text{gcd}(a, b) = am + bn$ for some integers m and n. Note. Multiples of GCD are Linear Combinations of a and b E.g. write $\text{gcd}(312, 125)$ as a linear combination $312m + 125n$ Solution. $\text{gcd}(312, 125) = \text{gcd}(312, 62) = \text{gcd}(312, 62) = 2 \cdot 125 + 62 \cdot \dots (1)$
 $\text{gcd}(312, 62) = \text{GCD}(62, 1) = 125 = 2 \cdot 62 + 1 \cdot \dots (2)$
 $\text{gcd}(62, 1) = 1$ Using (2).
 $1 = 125 + (-2) \cdot 62 = 125 + (-2)(312 - 2 \cdot 125)$ using (1) = $5125 + (-2) \cdot 312$.

FSM FSA NFA			FSM FSA NFA (cont)		Relations		
A finite-state machine $M = (S, I, O, f, g, s_0)$ consists of a finite set S of states a finite input alphabet I a finite output alphabet O a transition function f that assigns to each state and input pair a new state an output function g that assigns to each state and input pair an initial state s_0 . A state table is used to represent the values of the transition function f and the output function g for all (state, input).	FSMs with no output, but with some states designated as accepting states, are specifically designed for recognizing languages. A finite-state automaton $M = (S, I, f, s_0, F)$ consists of a finite set S of states, a finite input alphabet I , a transition function f that assigns a next state to every pair of state and input (so that $f: S \times I \rightarrow S$), an initial or start state s_0 , and a subset F of S consisting of final (or accepting) states. FSAs can be represented using either state tables or state diagrams, in which final states are indicated with a double circle. A finite state machine (FSM) with no output is called a finite state automata (FSA). A string x is said to be recognized (or accepted) by the machine $M = (S, I, f, s_0, F)$ if it takes the	A nondeterministic finite-state automaton $M = (S, I, f, s_0, F)$ consists of a finite set S of states A finite input alphabet I A transition function f that assigns a set of states to every pair of state and input (so that $f: S \times I \rightarrow P(S)$) An initial or start state s_0 A subset F of S consisting of final (or accepting) states. For every NFA there is an equivalent DFA. That is, if the language L is recognized by a NFA M , then L is also recognized by a DFA M_1 . We construct the DFA M_1 so that The start symbol of M_1 is $\{s_0\}$. The input set of M_1 is the same as the input set of M . Each state in M_1 is made from of a set of	A vocabulary (or alphabet) V is a finite, nonempty set of elements called symbols. A word (or sentence) over V is a string of finite length of elements of V . The empty string or null string, denoted by λ , is the string containing no symbols. The set of all words over V is denoted by V^* . A language over V is a subset of V^* . A phrase-structure grammar $G = (V, T, S, P)$ consists of a vocabulary V , a subset T of V consisting of terminal symbols, a start symbol S from V , and a finite set of productions P . The set $V - T$ is denoted by N . Elements of N are called nonterminal symbols. Every production in P must contain at least one nonterminal on its left side. Let $G = (V, T, S, P)$ be a phrase-structure grammar. The language generated by G (or the language of G), denoted by $L(G)$, is the set of all strings of terminals that are derivable from the starting state S . In other words, $L(G) = \{w \in T^* \mid S \xrightarrow{*} w\}$. EXAMPLE 5 Give a phrase-structure grammar that generates the set $\{0^n 1^n \mid n = 0, 1, 2, \dots\}$. The solution is the grammar $G = (V, T,$	A type 0 grammar has no restrictions on its productions. A type 1 grammar can have productions of the form $w_1 \rightarrow w_2$, where $w_1 = lAr$ and $w_2 = lwr$, where A is a nonterminal symbol, l and r are strings of zero or more terminal or nonterminal symbols, and w is a nonempty string of terminal or nonterminal symbols. It can also have the production $S \rightarrow \lambda$ as long as S does not appear on the right-hand side of any other production. A type 2 grammar can have productions only of the form $w_1 \rightarrow w_2$, where w_1 is a single symbol that is not a terminal symbol. A type 3 grammar can have productions only of the form $w_1 \rightarrow w_2$ with $w_1 = aB$ and either $w_2 = a$, where A and B are nonterminal symbols and a is a terminal symbol, or with $w_1 = S$ and $w_2 = \lambda$. EXAMPLE 9 It follows from Example 5 that $\{0^n 1^n \mid n = 0, 1, 2, \dots\}$ is a context-	A binary relation R on a set A and B is defined as R is a subset of $A \times B$. A relation is a subset of the cartesian product of two sets A and B , which is a set of ordered pairs. A $x B = \{(a, 1), (a, 2), (a, 3), (b, 1), (b, 2), (b, 3), (c, 1), (c, 2), (c, 3), (d, 1), (d, 2), (d, 3)\}$. A relation is usually written in set format: $R = \{(a, 2), (b, 1), (c, 1), (d, 3), (c, 2)\}$. We say that a is related to 2 in one of the following notations: $(a, 2)$ is $e R$, or a $R 2$.	1) A relation R on a set A is called reflexive if $(a, a) \in R$ for every element $a \in A$. 2) A relation R on a set A is called symmetric if $(b, a) \in R$ whenever $(a, b) \in R$ for all $a, b \in A$. A relation R on a set A such that $(a, b) \in R$ and $(b, a) \in R$, then $a = b$ is called antisymmetric. 3) A relation R on a set A is called transitive if whenever $(a, b) \in R$ and $(b, c) \in R$, then $(a, c) \in R$ for all $a, b, c \in A$. 4) Let R be a relation from a set A to a set B and S a relation from B to	Because this relation contains R , is reflexive, and is contained within every reflexive relation that contains R , it is called the reflexive closure of R . This new relation is symmetric and contains R . Furthermore, any symmetric relation that contains R must contain this new relation, because a symmetric relation that contains R must contain $(2, 1)$ and $(1, 3)$. Consequently, this new relation is called the symmetric closure of R . Let R be a relation on a set A . The connectivity relation R^* consists of the pairs (a, b) such that there is a path of length at least one from a to b in R . The transitive closure of a relation R equals the connectivity relation R^* . A relation on a set A is called an equivalence relation if it is reflexive, symmetric, and transitive. Two elements a and b that are related

Alternatively, a finite-state machine can be represented by a state diagram, which is a directed graph with labeled edges. Each state is represented by a circle, and arrows labeled with the input and output pair represent the transitions. The state table and state diagram both represent the finite state machine with $S = \{s_0, s_1, s_2, s_3\}$, $I = \{0, 1\}$, and $O = \{0, 1\}$.

initial state s_0 to a final state, that is, $f(s_0, x)$. The language recognized (or accepted) by M , denoted by $L(M)$, is the set of all strings that are recognized by M . Two finite-state automata are called equivalent if they recognize the same language. The final state of M_3 are s_0 and s_3 . The strings that take s_0 to itself are $\lambda, 0, 00, 000, \dots$. The strings that take s_0 to s_3 are a string of zero or more consecutive 0s, followed by 10, followed by any string. Hence, $L(M_3) = \{0^n, 0^n 10x \mid n = 0, 1, 2, \dots, \text{ and } x \text{ is any string}\}$

states in M_0 . Construct new states in M_1 by interpreting each unique output in the M_0 transition table as its singular own state, e.g. $s_1, s_2, \dots, s_n, \dots, \square, \square\#, \emptyset$. Given a state $\{s_1!, s_2!, \dots, s_n\# \}$ in M_1 and an input symbol x , the transitions from this state to the next is the union of transitions $f(s_1!, x), f(s_2!, x), \dots, f(s_n\#, x)$ from M_0 for the states that compose the state from $\square, \square\#$. The final states of M_1 are any sets that contain a final state of M_0 .

S, P), where $V = \{0, 1, S\}$, $T = \{0, 1\}$, S is the starting symbol, and the productions are $S \rightarrow 0S1 \ S \rightarrow \lambda$.

free language, because the productions in this grammar are $S \rightarrow 0S1$ and $S \rightarrow \lambda$.

a set C . The composite of R and S is the relation consisting of ordered pairs (a, c) , where $a \in A, c \in C$, and for which there exists an element $b \in B$ such that $(a, b) \in R$ and $(b, c) \in S$. We denote the composite of R and S by $S \circ R$. 5) Let R be a relation on the set A . The powers $R^n, n = 1, 2, 3, \dots$, are defined recursively by $R^1 = R$ and $R^{n+1} = R^n \circ R$. 6) The relation R on a set A is transitive if and only if $R^n \subseteq R$ for $n = 1, 2, 3, \dots$

by an equivalence relation are called equivalent. The notation $a \sim b$ is often used to denote that a and b are equivalent elements with respect to a particular equivalence relation. Let R be an equivalence relation on a set A . The set of all elements that are related to an element a of A is called the equivalence class of a . The equivalence class of a with respect to R is denoted by $[a]_R$. When only one relation is under consideration, we can delete the subscript R and write $[a]$ for this equivalence class. Let R be an equivalence relation on a set A . These statements for elements a and b of A are equivalent: (i) aRb (ii) $[a] = [b]$ (iii) $[a] \cap [b] \neq \emptyset$. A relation R on a set S is called a partial ordering or partial order if it is reflexive, antisymmetric, and transitive. A set S together with a partial ordering R is called a partially ordered set, or poset, and is denoted by (S, R) . Members of S are called elements of the

poset. When every two elements in the set are comparable, the relation is called a total ordering.

Boolean functions

<p>The complement of an element, denoted with a bar, is defined by $\overline{0} = 1$ and $\overline{1} = 0$. The variable x is called a Boolean variable if it assumes values only from B, that is, if its only possible values are 0 and 1. A function from B^n to B is called a Boolean function of degree n. $x \mid y$ (or $x \text{ NAND } y$): the expression that has the value 0 when both x and y have the value 1 and the value 1 otherwise. $x \downarrow y$ (or $x \text{ NOR } y$): the expression that has the value 0 when either x or y or both have the value 1 and the value 0 other- wise</p>	<p>$\overline{\overline{x}} = x$ Law of the double complement $x + \overline{x} = 1$ Idempotent laws $x \cdot x = x$ $x + 0 = x$ Identity laws $x \cdot 1 = x$ $x + 1 = 1$ Domination laws $x \cdot 0 = 0$ $0 + y = y$ x Commutative laws $xy = yx$ $(y + z) = (x + y) + z$ Associative laws $x(yz) = (xy)z$ $x + yz = (x + y)(x + z)$ Distri- butive laws $x(y + z) = xy + xz$ $\overline{\overline{xy}} = \overline{\overline{x}} + \overline{\overline{y}}$ De Morgan's laws $\overline{x + y} = \overline{x} \cdot \overline{y}$ $\overline{\overline{x} \cdot \overline{y}} = x + y$ Absorption laws $x(x + y) = x$ $x + \overline{x}y = x + y$ Unit property $x \cdot 1 = x$ Zero property</p>	<p>A literal is a Boolean variable or its complement. A minterm of the Boolean variables x_1, x_2, \dots, x_n is a Boolean product $y_1 y_2 \dots y_n$, where $y_i = x_i$ or $y_i = \overline{x_i}$. Hence, a minterm is a product of n literals, with one literal for each variable. The sum of minterms that represents the function is called the sum-of-pr- oducts expansion or the disjunctive normal form of the Boolean function. Find the sum-of- products expansion for the function $F(x, y, z) = (x + y)z$. Solution: We will find the sum-of- products expansion of $F(x, y, z)$ in two ways. First, we will use Boolean identities to expand the product and simplify. We find that $F(x, y, z) = (x +$</p>
--	---	--

$(x + y)z = xz + yz$
 Distributive law
 $x(y + z) = xy + xz$
 Identity law
 $x(y + z) = x(y + z) + (x + x)yz$
 Unit property
 $x(y + z) = x(y + z) + xy + xz$
 Distributive law
 $x(y + z) = xy + xz$
 Idempotent law. The resulting expansion is called the conjunctive normal form or product-of-sums expansion of the function. These expansions can be found from sum-of-products expansions by taking duals. Because every Boolean function can be represented using these operators we say that the set $\{ \cdot, +, - \}$ is functionally complete
