

Fever - classes of medication

Acetaminophen **Mechanism of action:** acts at hypothalamus to cause peripheral vasodilation, which enables sweating and allows body to rid excess heat
No anti-inflammatory action
Primary use: fever, mild to moderate pain, osteoarthritis

NSAID's Same mechanism of action as acetaminophen (for fever)
Because of acetaminophen's safety record (few drug interactions and side effects), it is first-line for fever
NSAID could be more appropriate if inflammation is also present (ibuprofen > ASA)
ASA is contraindicated in children ❌ Reye's Syndrome (ASA + virus + fever in child)

Adverse effects

NSAID nausea, dyspepsia, ulcer with long-term use, potential anti-platelet action, hypertension, increased risk of cardiac event with long-term use
Take with food
Caution in kidney disease, cardiovascular disease, GI conditions

Corticosteroids

Adverse effects (cont)

Acetaminophen very rare liver toxicity (max dose of 4g/24hours), avoid alcohol, interacts with warfarin (but doesn't ↑ bleeding on its own)

1st-Generation Antihistamines Significant sedation

2nd-Generation Antihistamines

Intranasal Corticosteroids nasal irritation, dryness and bleeding (epistaxis), bad taste, loss of smell

Decongestants oral – hypertension, anxiety, insomnia;
Phenylephrine, pseudoephedrine intranasal – nasal irritation, rebound congestion, rarely systemic effects

Penicillin anaphylaxis, diarrhea, nausea, vomiting, pain at injection site, superinfections, some (minor) drug interactions

Cephalosporins hypersensitivity, rash, itching, anaphylaxis,
Cefotaxime (3rd Gen.) diarrhea, vomiting, nausea, pain at injection site, some (minor) drug interactions
Must be given IV or IM (not orally)

Adverse effects (cont)

Tetracyclines diarrhea, yeast infections, nausea, vomiting, epi-gastric burning, yellow-brown teeth discolouration in young children (we don't prescribe for kids), photosensitivity
Can potentially interfere with oral contraceptives (recommend backup method)
Higher chance of superinfections because it is broad-spectrum

Macrolides : significant nausea, vomiting, diarrhea (take with food), some important drug interactions
Erythromycin Warfarin, cyclosporine, anticonvulsants (all via CYP450 inhibition/induction)
Fidaxomicin – new; for treatment of c. difficile; not absorbed, stays in GI tract
nausea, constipation, vomiting

Aminoglycosides ototoxicity, nephrotoxicity
Gentamicin

Adverse effects (cont)

Fluoroquinolones
Ciprofloxacin

nausea, diarrhea (can take with food), photosensitivity

Separate from minerals like calcium, iron, magnesium, aluminum (including supplements and antacids) by 2h

Serious adverse effects associated with fluoroquinolones: Tendinitis or tendon rupture (1.3-5.6 in 10,000)

Cardiac arrhythmias (15-57 in 100,000)

CNS effects ☑ seizures, tremors, altered mental state

Peripheral neuropathy

Sulfonamides
Sulfamethoxazole-Trimethoprim (SMZ-TMP, Septra®, Bactrim®, -DS)

nausea, vomiting, skin rashes, photosensitivity, anemia, crystalluria

Drink lots of water to prevent crystalluria

Monitor for: painful urination, abdominal pain, blood in urine, fever

Carbapenems
ertapenem, imipenem, meropenem

skin reactions, inflammation at injection site, diarrhea, nausea, vomiting

Clindamycin

High risk of superinfection (GI)

Adverse effects (cont)

Nitrofurantoin

Changes urine to orange colour

Must take with food

Metronidazole

Disulfiram reaction – flushing, tachycardia, shortness of breath, severe nausea & vomiting, throbbing headache, visual disturbance, confusion, dizziness

Occurs ~ 5-10 minutes after intake, lasts 30 mins ☑ several hours

Vancomycin

Ototoxicity and nephrotoxicity

Linezolid

lactic acidosis, myelosuppression (↓WBC and platelets), peripheral and optic neuropathy, serotonin syndrome, diarrhea,

Major drug interaction with any serotonergic drug, may need to discontinue until course of treatment finished, also inhibits MAO

Rifampin (RMP)

Rashes, blood dyscrasias, GI disturbances, liver damage, nephrotoxicity

Secretions coloured a reddish-orange (sweat, urine, sputum, tears)

Adverse effects (cont)

Amphotericin B

fever & chills during infusion, vomiting, headache, phlebitis, nephrotoxicity, hypokalemia, ototoxicity

Azole Antifungals
fluconazole, itraconazole, ketoconazole, miconazole, voriconazole

Rare hepatotoxicity – avoid alcohol, watch for jaundice, monitor liver enzymes

Nystatin

Oral thrush – swish and swallow oral suspension four times daily (works topically) (needs Rx)

Adverse effects (cont)

Classic Immuno-suppressant

Increased risk of infections, Increased risk of cancers such as lymphomas, cysts, and polyps

Frequency increases with intensity and duration of treatment, Kidney impairment, hepatic impairment, Hypertension, hyperlipidemia, CNS: tremor, headache, skin prickling sensation, GI: nausea, vomiting, abdominal pain, diarrhea, gingival hyperplasia, MSK: Muscle cramps, myalgia

Endocrine: Menstrual disturbances, gynecomastia, Hypertrichosis (abnormal amount of hair growth over body), Fatigue

Adverse effects (cont)

Chemotherapy

short term
Nausea/vomiting, Diarrhea or constipation, Mucositis/stomatitis, Myelosuppression, Hair growth alterations, Weight gain / weight loss, Taste alterations, Fatigue, Hepatic and renal changes, Cardiac function changes, Rash / skin changes / nail changes, High blood pressure

Long term
Infertility, Secondary malignancies, Heart failure, Osteoporosis, Pulmonary fibrosis, Cataracts, Peripheral neuropathy, Hearing loss, Fatigue, Endocrine abnormalities

Inflammation mediators

Histamines

Bradykinin

Leukotrienes

Cytokines

Interleukins

Prostaglandin

Inflammation classes of medication

Non-steroidal anti-inflammatory NSAID

Inhibit cyclo-oxygenase (COX), which reduces prostaglandin synthesis therefore inhibiting inflammation

Also have analgesic and antipyretic properties

For mild to moderate inflammation

Inflammation classes of medication (cont)

COX-1 – In all tissues, stomach lining (mucosa), involved in platelet aggregation

COX-2 more specific for inflammation

Ibuprofen

mild to moderate inflammation, fever, mild to moderate pain, dysmenorrhea, musculoskeletal pain, arthritis

Corticosteroids

Mimic endogenous cortisol, attempting to bring body back to homeostasis after a fight-or-flight response

Anti-inflammatory and immuno-suppressive

For severe inflammation

Serious systemic adverse effects limit use to emergencies and severe inflammation (multiple sclerosis, rheumatoid arthritis, auto-immune diseases)

Local administration, short-term use preferred whenever possible

Antibiotics - Classes of medication

Penicillins <i>-cillin</i>	Disrupt bacterial cell walls, Bactericidal Penicillin-binding protein: a protein only in bacterial cell walls that penicillin binds to which weakens the cell wall, allows fluid to enter and destroys the cell Penicillins contain a beta-lactam ring in its structure necessary for activity Many bacteria produce beta-lactamase (penicillinase) that is a natural defense to penicillin – it breaks the beta-lactam ring, leaving it ineffective therefore penicillin resistance
<i>Amoxicillin + Clavulanic Acid (Amoxiclav)</i>	Clavulanic acid inhibits β -lactamases (penicillinases) of some microorganisms to allow amoxicillin to be active against it Synergistic relationship

Antibiotics - Classes of medication (cont)

<i>Penicillin G Potassium (Pen G)</i>	Drug of choice against streptococci, pneumococci, staphylococci, gonorrhea and syphilis (given IV or IM)
Cephalosporins <i>-ce(f)ph</i>	Related to penicillins (1st gen. also have beta-lactam ring) Also inhibit cell wall synthesis, Bactericidal Classified according to "generation" (1 - 4) General Rules 1st generation not effective against bacteria producing beta-lactamase More potent as go up in generation Fewer similarities with penicillins as go up in generation Higher generations reserved for known resistant infections
<i>Cefotaxime (3rd Gen.)</i>	Has broad-spectrum activity against gram-negative organisms; for serious infections of lower respiratory tract, CNS, genitourinary system, bones, blood, and joints

Antibiotics - Classes of medication (cont)

Tetracyclines <i>doxycycline, minocycline, tetracycline</i> <i>-cycline</i>	Inhibit bacterial protein synthesis, Bacteriostatic Broad-spectrum (both gram-positive and negative) Usually given orally (PO) Should not be given at the same time as iron, calcium, magnesium (ions bind to drug so it can't absorb) – separate by 2h
<i>Tetracycline</i>	Used for Rocky Mountain spotted fever, h.pylori infections, acne vulgaris, chlamydia
Macrolides <i>azithromycin, clarithromycin, erythromycin, fidaxomicin</i> <i>-thromycin</i>	Inhibit bacterial protein synthesis, Some are bactericidal, some bacteriostatic No structural similarities to penicillin – zero chance of cross-reactivity
<i>Erythromycin</i>	Used for upper and lower respiratory tract infections, whooping cough, diphtheria, or for other infections in patients who cannot take penicillins

Antibiotics - Classes of medication (cont)

Aminoglycosides Inhibit bacterial protein synthesis and cause abnormal protein synthesis, *amikacin*, *gentamicin*, *streptomycin*, *tobramycin* Dose-dependent bactericidal Very effective, usually reserved for serious infections (like tuberculosis) or when other antibiotics have failed Require therapeutic drug monitoring – levels must be in specific range to be effective, but not toxic Injection or topical

Gentamicin Used for serious (life-threatening) infections or when other antibiotics have failed (also topically as eye drops and creams/ointments – this would not require therapeutic drug monitoring)

Antibiotics - Classes of medication (cont)

Fluoroquinolones Affect bacterial DNA synthesis, Bactericidal Most often used orally (also ear, eye) Absorption is affected by minerals (calcium, iron, magnesium) and need to be separated (~2h) Generally not used in children – affects cartilage development

Ciprofloxacin Used commonly for respiratory, urinary, ophthalmic, gastrointestinal, and gynecological infections – high usage in community/out-patient

Sulfonamides Suppress bacterial growth by inhibiting essential folic acid needed within the cell, Bacteriostatic Broad spectrum, older class ☑ more resistance seen Orally and topically (acne) “Sulfa” is also a common “allergy”

Antibiotics - Classes of medication (cont)

Sulfamethoxazole-Trimethoprim Both drugs inhibit essential folic acid synthesis; work synergistically (a pharmacodynamic interaction) (*SMZ-TMP*, *Septera®*, *Bactrim®*, *-DS*) Used to treat urinary tract infections

Carbapenems Relatively new-ish Contain beta-lactam ring and inhibit cell wall synthesis (like penicillins) The beta-lactam ring is very resistant to destruction by penicillinase Broad spectrum – and very effective; as a newer class, they are being reserved for resistant infections (like MRSA, etc.)

Miscellaneous VIPs

Clindamycin protein synthesis inhibitor; bacteriostatic Used topically (acne), oral or IV for serious systemic infections High risk of superinfection (GI)

Antibiotics - Classes of medication (cont)

Nitrofurantoin inhibits protein, RNA, DNA, and cell wall synthesis; bactericidal
Excreted unchanged through the kidney (no metabolism), therefore used only for urinary tract infections
Changes urine to orange colour
Must take with food

Metronidazole destroys bacterial DNA; bactericidal
For anaerobic bacteria
NO ALCOHOL USE (even small amounts present in cough syrup or mouthwash)

Antibiotics - Classes of medication (cont)

Vancomycin inhibits cell wall synthesis; bactericidal (through different mechanism than aminoglycosides)
Reserved for severe infections that are resistant to anything else ☑ usually only used in hospital (methicillin-resistant staph. aureus - MRSA)
Injection or oral
If IV given too quickly ☑ Red Man Syndrome (flushing, red face, hypotension) ☑
slow down infusion
Therapeutic drug monitoring required (like aminoglycosides)

Linezolid inhibits bacterial protein synthesis
Use to treat vancomycin-resistant enterococcus (VRE), pneumonia or skin infections caused by MRSA i.e. Severe infections resistant to other antibiotics

Allergies- Classes of Medication

Antihistamines

Allergies- Classes of Medication (cont)

1st-Generation Antihistamines Block H1 receptors
Shorter acting, cause more drowsiness, and work faster than 2nd Generation
Used mostly to treat allergic response
Diphenhydramine and *chlorpheniramine* most common
Have anticholinergic effects
Significant sedation – some use as a sleep aid

2nd-Generation Antihistamines *Cetirizine (Reactine®)*, *loratidine (Claritin®)*, *desloratidine (Aerius®)*, *fexofenadine (Allegra®)*

Intranasal Corticosteroids To reduce inflammation in nasal mucous membranes, and local immunosuppression
Used daily to prevent symptoms
Can take up to 2 weeks for full effect
Local administration prevents systemic side effects

Allergies- Classes of Medication (cont)

Decongestants Sympathomimetics – stimulants – cause vasoconstriction and reduction of mucous production
Phenylephrine, pseudoephedrine For immediate relief of nasal congestion – oral or intranasal
Short term-use only – rebound congestion if longer than 3-5 days (intranasal)

Drugs for Anaphylaxis

Epinephrine Stimulates both α and β adrenergic receptors
Via α -receptors: counters the high vascular permeability that occurs during anaphylaxis that leads to loss of intravascular fluid and hypotension
Via β -receptors: causes bronchial smooth muscle relaxation and relieves bronchospasm, dyspnea, and wheezing
Also alleviates pruritus, urticaria, and angioedema

Anti-fungals - Classes of medication

Amphotericin B Binds to fungal cell membranes, making them leaky, Given IV

Azole Antifungals Alter fungal cell membranes by depleting ergosterol
fluconazole, itraconazole, ketoconazole, miconazole, voriconazole
Used orally, topically, injection; fluconazole available OTC
Safer than amphotericin B
Most often for vaginal candidiasis, athlete's foot, or thrush
metronidazole is NOT an azole antifungal

Miscellaneous

Ciclopirox topical med used for fungal nail or scalp infections (nail polish or shampoo)

Terbinafine oral med for fungal nail infections

Nystatin cream available without prescription for many topical fungal infections (ringworm, diaper rash)

Anti-Virals -Classes of medication

HIV Because of antiretroviral drugs, HIV patients are able to live symptom-free for much longer with very low counts of the retrovirus
Antiretroviral drugs block the HIV replication cycle

Anti-Virals -Classes of medication (cont)

HAART – Goal is to reduce plasma HIV to its lowest possible level - highly active antiretroviral therapy
HIV still remains in the lymph nodes
Blood and lymph are separate rivers that cross occasionally
Use different classes of antiretrovirals at same time to reduce resistance
Each class 'attacks' different step of replication cycle

Herpes Infections

HSV1: oral cold sores

HSV2: genital ulcerations

Zoster: shingles (due to previous varicella-zoster infection)

Acyclovir, famciclovir, valacyclovir Mostly controlled by oral therapy of antivirals – taken at first sign of outbreak, continued for short term
These antivirals prevent viral DNA synthesis
Very well tolerated – take with food

Over the Counter medications for Herpes

Lipactin® - can reduce pain, may speed healing
heparin + zinc Mechanism does not match pathophysiology

Anti-Virals -Classes of medication (cont)

Abreva® - prevents viral entry into cells, stops spread if caught early (can reduce duration of cold sore by ~1 day)

Influenza BEST PROTECTION = VACCINATION
Amantadine, and neuraminidase inhibitors (oseltamivir and zanamivir) Antiviral drugs may decrease severity of symptoms of influenza and may shorten symptom time by a couple days IF taken within first 48 hours
 Generally used only in patients at high risk of complications from influenza

Immunosuppression - Classes of Medication

Calcineurin Inhibitors "Classic" immuno-suppressants used for transplants (or topically for psoriasis)
Cyclosporine, tacrolimus, pimecrolimus (topical) Disrupt T-cell function by binding to calcineurin
 They are not specific – suppress the ENTIRE immune system ☑ patient is very susceptible to any other infection
 Extensive monitoring for detailed WBC counts and signs of infection (see slide on monitoring)

Immunosuppression - Classes of Medication (cont)

Corticosteroids Anti-inflammatory and immunosuppressant activity
 Often used to control exacerbations of condition such as asthma, rheumatoid arthritis, MS, etc.
 Pulse therapy (very high doses, gradual taper) to minimize side effects
 Many, many side effects

Biologics medications produced using biological processes in living organisms such as yeast and bacteria
 Have active pharmaceutical ingredients that cannot reasonably be synthesized by chemical means (too complicated)
 Are complex, large molecules derived from living sources and produced through a number of intricate steps
 Biologics can be immunosuppressant or immunostimulant (very specifically) or replace a substance that is missing (insulin)

Immunosuppression - Classes of Medication (cont)

Vaccines, Blood products, Hormones & growth factors, Enzymes Gene therapy, Cancer treatments

Chemotherapy

Cytotoxic drugs traditional; interfere with or damage DNA, causing apoptosis (programmed cell death)

Hormonal therapy not cytotoxic; effects mediated through hormonal receptors (deprivation) – for hormone-responsive cancer (breast, prostate, etc.)

Immuno-therapy monoclonal antibodies, vaccines; non-specifically boost immune system to help eradicate cancer (interferon alfa)

Targeted agents monoclonal antibodies, tyrosine-kinase inhibitors (TKIs); the future of treatment – to target cancer cells only

Tuberculosis medications

Rifampin (RMP) Most potent anti-TB drug available
 Good bactericidal activity, prevents acquired drug resistance and is very important in preventing relapse
 Current doses are based on studies performed in the 1960s, when the lowest effective dose was used because of the high cost of the drug; concerns now that dose is too low -> current trials -> dosing recommendations may change
