

Data Binding

String Interpolation	{{}} the use of double curly braces. It will be interpreted and converted into a string. What ever is used in the string it is outputted. One direction
Property Binding	[] Bind to the property of an element or component. Property element is an NG2 property ie. [value] = "name". Flow into
Event Binding	() react to changes from the dom
Two way data binding	[(ngModel)] for both input and output, eg [(ngModel)]="name"

Component Communication

@Input("alias") <property>	Used to receive input external to this component
@Output("alias") <event>	Used to communicate out of a component. Use EventEmitter<?>. eventEmitter.emit(type)
Listening to events	(eventEmitName)="bind = \$event" the \$event allows you to set and handle the output from the component

When listening to event being emitted its a good idea to use the built in conversion that type script provides to map the event proxy object onto the domain object being projected.
