## Renal System Cheat Sheet by noush via cheatography.com/213565/cs/46486/

### Definition

The organ system in charge of regulating fluid balance, removing waste from the circulation, and excreting urine is the renal system which is also sometimes referred to as the urinary system.

### Main Functions

Filters waster from the blood (urea/toxins) Regulated blood pressure Hormone production (erythropoietin, renin) Excreted drugs and toxins Control blood pH Maintains electrolyte levels Keeps bones healthy Eliminates metabolic byproducts Supports blood osmolarity Glucongenesis

### Nephron Physiology

Filtration	Occurs in the glomerulus where fluid (filtrate) is forced in the Bowman's capsule by blood pressure. Blood cells and plasma proteins are too large to get filtered, but water, glucose, urea, amino acids, and small molecules all pass through.
Reabso- rption	It is in the proximal convoluted tubule (PCT) where substances such as water, glucose, Na+, K+, Cl-, and amino acids are all reabsorbed back into the blood. The descending loop includes water only and the ascending loop has Na+ and Cl

### Nephron Physiology (cont)

Secretion	Occurs mostly in the distal
	convoluted tubule (DCT), and it
	removed substances including
	H+, K+, NH4+, and some drugs
	from the blood into filtrate to be
	excreted.
Excretion	In this step, the tribe follows a
	track from the collecting ducts -
	> renal papilla -> minor calyx ->
	major calyx -> renal pelvis ->
	ureter -> and finally to the
	bladder.
Anatomy of	the Renal System

Main Organs	Internal (Kidney)
Kidneys	Cortex
Ureters	Medulla
Urethra	Renal Pelvis
Urinary Bladder	Renal Artery
	Renal Papilla
	Calyces
	Renal Vein

Hormones			
Hormone	Function	Source	
ADH	Water reabso- rption	Posterior Pituitary	
Aldost- erone	Na+ reabso- rption	Adrenal Cortex	
Erythr- opoietin	RBC production	Kidney	
Renin	Blood pressure regulation	Juxtaglom- erular Cells	
Calcutriol	Vitamin D activation	Kidney	

Common Diseases				
Chronic Kidney Disease	Kidney Cancer	Diabetes		
Unrinary Tract Infection	Glomerulonep- hritis	Interstitial Cystitis		
Hypertension	Uremia	Urinalysis		
Acidosis	Kidney Stones	Pyelon- ephritis		
Ecoptic Kidney	Polycystic Kidney Disease	Kidney Failure		

### Cortical vs Juxtamedullary Nephrons Core Cortical Juxtamedu-Element llary Location **Renal Cortex** Glomerulus Function Absorption Concenand filtration trates urine Percentage 85% 15% Blood Peritubular Vasa Recta Supply Cappilaries Association Homeostasis Water conservation

### **Psychological Factors**

### Fun Facts

Did you know that your kidneys filter your whole blood volume around 60 times every day? That is around 1.2 to 1.5 liters of blood every minute.

If all of the filtering tubules (nephrons) of one kidney were stretched out, they would be approximately 5 miles long. While most individuals are born with two kidneys, it is possible to live a healthy life with only one. The surviving kidney frequently responds by getting bigger and working harder. The human bladder is capable of holding a remarkable amount of pee. Approximately 300-500 milliliters (1.5 to 2 cups) before you feel a strong want to go. The name "renal" is derived from the Latin word "renes," which means kidney.

Reduced GFR and renal vasoconstriction are the results of acute stress activating the SNS and HPA axis. In order to boost blood pressure and preserve fluid, it promotes renin release, which activates RAAS. Prolonged cortisol rise brought on by chronic stress contributes to glomerular damage and hypertension. Water retention may result from elevated ADH levels brought on by stress. In terms of behavior, stress can deteriorate kidney function by causing excessive salt intake, dehydration, and bad habits like excessive caffeine or alcohol consumption..
