

### Intro

|                             |                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------|
| Myocardium                  | middle of heart wall, contains cardiac muscle                                                                   |
| How are CM cells connected? | intercalated discs, forms desmosomes and gap-junctions                                                          |
| Functional Syncytium        | group of CM cells that contract in coordination with each other (gap junctions)                                 |
| Autorhythmicity             | creates its own electrical activity (no NS input)                                                               |
| Pacemaker Cells             | creates pacemaker activity, grouped together in nodes                                                           |
| Cardiac Contractile Cells   | 99% of cardiac muscle cells, actually performs contraction but is not autorhythmic                              |
| Other Characteristics       | involuntary (autonomic neuro fibers), striated, lots of mito + myoglobin, longer AP than smooth/skeletal muscle |

### Pacemaker Flow

|                            |                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------|
| SA Node                    | 70 APs/min, main node                                                               |
| Where is SA node?          | right atrium near superior vena cava                                                |
| AV Node                    | 50 APs/min, follows SA node                                                         |
| Where is AV node?          | base of right atrium                                                                |
| Bundle of His              | tract of pacemaker cells that start at AV node -> ends at left and right ventricles |
| Purkinje Fibers            | 30 APs/min, follows SA node                                                         |
| Where are Purkinje Fibers? | from end of Bundle of His through ventricular myocardium                            |
| Interatrial Pathway        | pacemaker pathway from right to left atrium                                         |

### Pacemaker Flow (cont)

|                                  |                                                            |
|----------------------------------|------------------------------------------------------------|
| Internodal Pathway               | pacemaker pathway from SA node to AV node                  |
| AV Nodal Delay                   | activity delay of 100ms going through AV node              |
| Why is AV Nodal Delay important? | allows for ventricles to contract after atrial contraction |

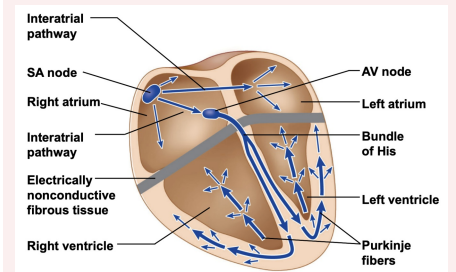

### Pacemaker Activity

|                                    |                                                                                                                                      |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| Nodes                              | controls rate and coordination of contractions                                                                                       |
| How many nodes?                    | 2 nodes, SA and AV                                                                                                                   |
| Pacemaker potentials               | depolarization of membrane potential until threshold (triggers AP)                                                                   |
| First half of pacemaker potential  | funny channels open -> Na <sup>+</sup> in, K <sup>+</sup> channels close (K <sup>+</sup> remains inside)                             |
| Second half of pacemaker potential | funny channels close, T-type Ca <sup>2+</sup> channels open -> takes potential to threshold                                          |
| Threshold                          | T-type Ca <sup>2+</sup> channels close, L-type Ca <sup>2+</sup> channels open -> potential reaches peak                              |
| Falling Phase                      | K <sup>+</sup> channels open (K <sup>+</sup> out), L-type Ca <sup>2+</sup> channels close -> fall back to original potential         |
| Major ions for pacemaker activity  | K <sup>+</sup> , Na <sup>+</sup> , Ca <sup>2+</sup>                                                                                  |
| Timing                             | both Ca <sup>2+</sup> channels are crucial for keeping rhythm (T-type channels: gradual depolarization, L-type: fast depolarization) |

### Pacemaker Activity (cont)

|                           |       |
|---------------------------|-------|
| Pacemaker potential value | -60mV |
|---------------------------|-------|

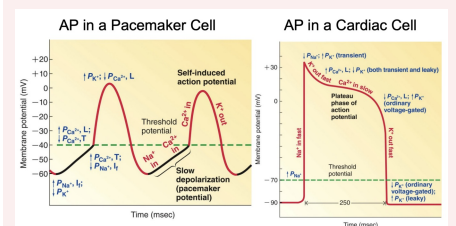

### Excitation Pathway

### Contractile Cardiac Muscle Cells

|                             |                                                                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Resting potential value     | -90mV                                                                                                                      |
| Rapid rise                  | opening fast Na <sup>+</sup> channels, Na <sup>+</sup> in                                                                  |
| Brief repolarization        | limited K <sup>+</sup> efflux, coupled with inactivation of Na <sup>+</sup> channel                                        |
| Plateau Phase               | Ca <sup>2+</sup> entry (opens L-type channels), coupled with reduced K <sup>+</sup> efflux (K <sup>+</sup> channels close) |
| Rapid falling               | opening ordinary voltage-gated K <sup>+</sup> channels (K <sup>+</sup> out)                                                |
| Resting potential           | back to resting potential by closing ordinary K <sup>+</sup> channels and opening leaky K <sup>+</sup> channels            |
| AP and Contractile response | contraction happens during plateau phase                                                                                   |

### Contractile AP vs. Pacemaker AP

### Excitation-Contraction Coupling

Dyhydropyridine receptors acts like voltage-gated  $\text{Ca}^{2+}$  channels. When AP reaches T-tubules, these receptors activate and allows  $\text{Ca}^{2+}$  flow

Sarcoplasmic Reticulum entry of  $\text{Ca}^{2+}$  causes calcium release from Sarcoplasmic Reticulum

Contraction number of activated cross-bridges is proportional to  $\text{Ca}^{2+}$  conc. in cytosol

Calcium-Induced Calcium-Release opening of L-type  $\text{Ca}^{2+}$  channels  $\rightarrow$  activation of dyhydropyridine receptors  $\rightarrow$  amplified release of  $\text{Ca}^{2+}$  from sarcoplasmic reticulum

Refractory Period and Contraction refractory period and length/strength of contraction is directly proportional (longer refractory period = contractile length/strength increases)
