A Table of Measure

Measurement	Sensor	Temperature	Timestamp
iot-oven	S1	290	16339536000000000000
iot-oven	S2	105	16339536150000000000
iot-oven	S1	305	16339536600000000000
iot-oven	S2	120	16339536750000000000

Basic Filtering

```
from(bucket: "training")
  |> range( start: v.time RangeStart, stop:
v.time RangeStop)
    |> filter(fn: (r) => r._measurement == " - 
iot -ov en")
      |> filter(fn: (r) => r._field == " tem per - 
atu re")
        |> filter(fn: (r) => r.sensor == " S2")
          |> filter(fn: (r) => r._value < 100)
```

The **range** clause allows to filter by time creating a time window.
The **filter** clause reduces the amount of records and can be applied on the measurements, fields, tags, and field/tag keys.

Functions

Flux transformations take a stream of tables as input, transform the data in some way, and output a stream of tables.

Aggregation

```
from(bucket: "training")
  |> range( start: v.time RangeStart, stop:
v.time RangeStop)
    |> filter(fn: (r) => r._measurement == " - 
iot -ov en")
      |> group( columns: ["_field"])
        |> mean()
```

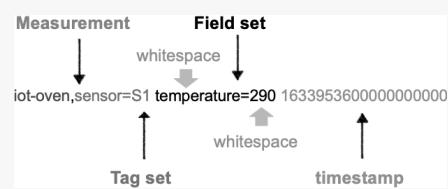

Flux aggregate functions are transformations aggregate values from input tables in some way.

Selector

```
from(bucket: "training")
  |> range( start: v.time RangeStart, stop:
v.time RangeStop)
    |> filter(fn: (r) => r._measurement == " - 
iot -ov en")
      |> filter(fn: (r) => r.sensor == " S1")
        |> group( columns: ["_field"])
          |> last()
```

Flux selector functions are transformations that return one or more record per input table.

Line Protocol

Advanced Windowing

```
from(bucket: "training")
  |> range( start: v.time RangeStart, stop:
v.time RangeStop)
    |> filter(fn: (r) => r._measurement == " - 
iot -ov en")
      |> filter(fn: (r) => r._field == " tem per - 
atu re")
        |> filter(fn: (r) => r.sensor == " S1")
          |> aggregateWindow(every: 2m, fn: mean)
```

`aggregateWindow()` downsamples data by grouping data into fixed windows of time and applying an aggregate or selector function to each window.

NOTE The flag `createEmpty: false` can be used to consider only the windows that contains data (its default value is `true`)

Map and Custom Functions

```
from(bucket: "training") ...
  |> map(fn: (r) => ({ r with
    correctedValue: r._value - 5.0 }))
```

Note the `r with` clause maintains all the original columns and adds the new one.

Custom pipe forwardable function

```
adjValues = (tables=<-, x) =>
  tables
    |> map(fn: (r) => ({ r with
      correctedValue: r._value + x }))
from(bucket: "training")
  |> range( start: v.time RangeStart, stop:
v.time RangeStop)
    |> filter(fn: (r) => r._measurement == " - 
iot -ov en")
      |> adjValues(x: -5.0)
```

Most Flux functions manipulate data piped-forward into the function. In order for a custom function to process piped-forward data, one of the function parameters must capture the input tables using the `<-` pipe-receive expression.

Joins

Conditional Expressions

```
... |> map(fn: (r) => ({
    r with _value:
        if r._value
== true then 1
        else 0 }))
```

Conditional expressions evaluate a boolean-valued condition. If the result is true, the expression that follows the then keyword is evaluated and returned.

```
from(bucket: "training")
...
join(tables: {s1: hs1, s2: hs2}, on: ["_time"], method: "inner")
```

The join() function merges two or more input streams, whose values are equal on a set of common columns, into a single output stream.
