Data Sources - read (cont)

option csv sep (default ,): sets a single character as a separator for each field and value.

quote (default ") : sets a single character used for escaping quoted values where the separator can be part of the value. If you would need to set not null but an empty string. This behaviour is different from `com.databricks.spark.csv`.

escape (default \): sets a single character used for escaping quotes inside an already quoted value. `charToEscapeQuoteEscaping` is a single character used for escaping the escape for the quote character. The default value is escape character when escape and quote are the same, otherwise. **comment** (default empty string): sets a single character used for skipping lines beginning with this character. By default, it is `#`.

header (default false): uses the first line as names of columns.

inferSchema (default false): infers the input schema automatically from data. It requires one extra pass over the data.

mode (default PERMISSIVE): allows a mode for dealing with corrupt records during parsing. It supports the following case-insensitive modes:

- PERMISSIVE** : sets other fields to null when it meets a corrupted record, and puts the malformed string into a field configured by `columnNameOfCorruptRecord`. To keep corrupt records, an user can set a string type field named `columnNameOfCorruptRecord` in an user-defined schema. If a schema does not have this field, it drops corrupt records during parsing. When a length of parsed CSV tokens is shorter than an expected length of a schema, it sets `columnNameOfCorruptRecord` to null.
- DROPMALFORMED** : ignores the whole corrupted records.
- FAILFAST** : throws an exception when it meets corrupted records.

nullValue (default empty string): sets the string representation of a null value. Since 2.0.1, this applies to all supported types including `String`.

nanValue (default NaN): sets the string representation of a non-number value.

dateFormat (default yyyy-MM-dd): sets the string that indicates a date format. Custom date formats follow the formats at `java.text.SimpleDateFormat` to date type.

timestampFormat (default yyyy-MM-dd'T'HH:mm:ss.SSSXXX): sets the string that indicates a timestamp format. Custom date formats follow the formats at `java.text.SimpleDateFormat`. This applies to timestamp type.

maxColumns (default 20480): defines a hard limit of how many columns a record can have. **maxCharsPerColumn** (default -1): defines the maximum number of characters allowed for any given value being read. By default, it is -1 meaning unlimited length.

multiLine (default false): parse one record, which may span multiple lines.

encoding (default UTF-8): decodes the CSV files by the given encoding type.

ignoreLeadingWhiteSpace (default false): a flag indicating whether or not leading whitespaces from values being read should be ignored.

ignoreTrailingWhiteSpace (default false): a flag indicating whether or not trailing whitespaces from values being read should be ignored.

positiveInf (default Inf): sets the string representation of a positive infinity value.

negativeInf (default -Inf): sets the string representation of a negative infinity value.

columnNameOfCorruptRecord (default is the value specified in `spark.sql.columnNameOfCorruptRecord`): allows renaming the name of the column created by PERMISSIVE mode. This overrides `spark.sql.columnNameOfCorruptRecord`.

Data Sources - read (cont)

json **mode** (default PERMISSIVE): allows a mode for dealing with corrupt records during parsing.

PERMISSIVE : sets other fields to null when it meets a corrupted record, and puts the malformed string into a field configured by column corrupt records, an user can set a string type field named `columnNameOfCorruptRecord` in an user-defined schema. If a schema does not records during parsing. When inferring a schema, it implicitly adds a `columnNameOfCorruptRecord` field in an output schema.

DROPMALFORMED : ignores the whole corrupted records.

FAILFAST : throws an exception when it meets corrupted records.

columnNameOfCorruptRecord (default is the value specified in `spark.sql.columnNameOfCorruptRecord`): allows renaming the new field by PERMISSIVE mode. This overrides `spark.sql.columnNameOfCorruptRecord`.

dateFormat (default yyyy-MM-dd): sets the string that indicates a date format. Custom date formats follow the formats at `java.text.SimpleDateFormat` type.

timestampFormat (default yyyy-MM-dd'T'HH:mm:ss.SSSXXX): sets the string that indicates a timestamp format. Custom date formats follow `SimpleDateFormat`. This applies to timestamp type.

multiLine (default false): parse one record, which may span multiple lines, per file

primitivesAsString (default false): infers all primitive values as a string type

prefersDecimal (default false): infers all floating-point values as a decimal type. If the values do not fit in decimal, then it infers them as double

allowComments (default false): ignores Java/C++ style comment in JSON records

allowUnquotedFieldNames (default false): allows unquoted JSON field names

allowSingleQuotes (default true): allows single quotes in addition to double quotes

allowNumericLeadingZeros (default false): allows leading zeros in numbers (e.g. 00012)

allowBackslashEscapingAnyCharacter (default false): allows accepting quoting of all character using backslash quoting mechanism

allowUnquotedControlChars (default false): allows JSON Strings to contain unquoted control characters (ASCII characters with value less than 32 or feed characters) or not.

Data Source - write (cont)

`saveAsTable(tableName: String): Unit` Saves the content of the DataFrame as the specified table.

String): Unit

In the case the table already exists, behavior of this function depends on the save mode, specified by the mode function (default mode is Overwrite, the schema of the DataFrame does not need to be the same as that of the existing table.

When mode is Append, if there is an existing table, we will use the format and options of the existing table. The column order in the DataFrame doesn't need to be same as that of the existing table. Unlike `insertInto`, `saveAsTable` will use the column names to find the correct

```
scala> Seq((1, 2)).toDF("i", "j").write.mode("overwrite").saveAsTable("t1")
scala> Seq((3, 4)).toDF("i", "j").write.mode("append").saveAsTable("t1")
```

```
scala> sql("select * from t1").show
```

```
+---+---+
```

```
| i| j|
```

```
+---+---+
```

```
| 1| 2|
```

```
| 4| 3|
```

```
+---+---+
```

In this method, save mode is used to determine the behavior if the data source table exists in Spark catalog. We will always overwrite the data source (e.g. a table in JDBC data source) if the table doesn't exist in Spark catalog, and will always append to the underlying data source if the table already exists.

When the DataFrame is created from a non-partitioned HadoopFsRelation with a single input path, and the data source provider is Hive builtin SerDe (i.e. ORC and Parquet), the table is persisted in a Hive compatible format, which means other systems like Hive can read it. Otherwise, the table is persisted in a Spark SQL specific format.

<https://apollopod.com>

Data Source - write (cont)

`insertInto(tableName: String): Unit`

Inserts the content of the DataFrame to the specified table. It requires that the schema of the DataFrame is the same as the table.

Unlike `saveAsTable`, `insertInto` ignores the column names and just uses position-based resolution. For example:

```
scala> Seq((1, 2)).toDF("i", "j").write.mode("overwrite").saveAsTable("t1")
scala> Seq((3, 4)).toDF("j", "i").write.insertInto("t1")
scala> Seq((5, 6)).toDF("a", "b").write.insertInto("t1")
scala> sql("select * from t1").show
+-----+
|  i  |  j  |
+-----+
|  5  |  6  |
|  3  |  4  |
|  1  |  2  |
+-----+
```

Because it inserts data to an existing table, format or options will be ignored.

```
DataFrameWriter.format(...).mode(...).option(...).partitionBy(colNames: String).bucketBy(numBuckets: Int, colNames: String).sortBy(colName: String, colNames: String*).save(path: String)
```

```
DataFrameWriter.format(...).mode(...).option(...).partitionBy(colNames: String).bucketBy(numBuckets: Int, colNames: String).sortBy(colName: String, colNames: String*).saveAsTable/insertInto(tableName: String)
```

To get `DataFrameWriter`, use `dataFrame.write`

Expressions (cont)

Relational expressions `expr("(((someCol + 5) * 200) - 6) < otherCol")`

An expression is a set of transformations on one or more values in a record in a DataFrame. Think of it like a function that takes as input one or more values, and then potentially applies more expressions to create a single value for each record in the dataset. Importantly, this "single value" can actually be a Map or Array.

Change the Column Data Type - Column

cast(to: String): Casts the column to a different data type, using the canonical string representation of the type. The supported types are: **string**, **long**, **float**, **double**, **decimal**, **date**, **timestamp**.

Column

```
// Casts colA to integer.  
df.select(col("colA").cast("int"))
```

org.apache.spark.sql.Dataset - others (cont)`summary(statistics: String*): DataFrame`

Computes specified statistics for numeric and string columns. Available statistics are:
- count - mean - stddev - min - max - arbitrary approximate percentiles specified as a percentage
`ds.summary().show()`

```
// output:  
// summary age  height  
// count  10.0  10.0  
// mean   53.3  178.05  
// stddev 11.6  15.7  
// min    18.0  163.0  
// 25%    24.0  176.0  
// 50%    24.0  176.0  
// 75%    32.0  180.0  
// max    92.0  192.0
```

```
ds.summary("count", "min", "25%", "75%", "max").show()
```

```
// output:  
// summary age  height  
// count  10.0  10.0  
// mean   53.3  178.05  
// min    18.0  163.0  
// 25%    24.0  176.0  
// 75%    32.0  180.0  
// max    92.0  192.0
```

To do a summary for specific columns first select them:

```
ds.select("age", "height").summary().show()
```

org.apache.spark.sql - Transformations (cont)

`union(other: Dataset[T]): Dataset[T]` Returns a new Dataset containing union of rows in this Dataset and another Dataset. This is equivalent to UNION ALL in SQL. To do a SQL-style set union (that does deduplication of elements), use this function for Dataset[T]. Notice that the column positions in the schema aren't necessarily matched with the fields in the strongly typed objects in a Data columns by their positions in the schema, not the fields in the strongly typed objects. Use `unionByName` to resolve columns by name.

```
val df1 = Seq((1, 2, 3)).toDF("col0", "col1", "col2")
val df2 = Seq((4, 5, 6)).toDF("col1", "col2", "col0")
df1.union(df2).show

// output:
// +----+----+----+
// |col0|col1|col2|
// +----+----+----+
// |  1|  2|  3|
// |  4|  5|  6|

`to_timestamp(s: Column, fmt: String): Column` Convert time string to a Unix timestamp (in seconds) with a specified format (see [<http://docs.oracle.com/javase/7/docs/api/java/sql/Date.html>]) to Unix timestamp (in seconds), return null if fail.
The format here is the format, which is used by timestamp to be saved in DF.
`DF.show()` will display the timestamp in default format `yyyy-MM-dd HH:mm:ss`

Working with Aggregate - RelationalGroupedDataset (cont)

`pivot(pivotColumn: String): RelationalGroupedDataset` Pivots a column of the current DataFrame and performs the specified aggregation. There are two versions of pivot function: `pivot` and `pivot_longer`. `pivot` specifies the list of distinct values to pivot on, and one that does not. The latter is more concise but less efficient, because it stores the list of distinct values internally.

Working with Window - functions (cont)

`cume_dist()`: Column Window function: returns the cumulative distribution of values within a window partition, i.e.
 $N = \text{total number of rows in the partition}$
 $\text{cumeDist}(x) = \text{number of values before (and including) } x / N$

```
import org.apache.spark.sql.expressions.Window
import org.apache.spark.sql.functions.colval
windowSpec = Window.partitionBy("CustomerId", "date").orderBy(col("Quantity").desc).rowsBetween(Window.unboundedPreceding, Window.curre

val purchaseRank = rank().over(windowSpec)

dfWithDate.where("CustomerId IS NOT NULL").orderBy("CustomerId")
.select(
  col("CustomerId"),
  col("date"),
  col("Quantity"),
  purchaseRank.alias("quantityRank")).show()
```
