Cheatography

Lua Scripting 5.1 Cheat Sheet

by SrGMC via cheatography.com/62984/cs/16090/

Types

number

string

boolean

table

function

userdata

thread

nil

Variable type can be obtained with type(variable)

Note: Table index starts at 0, but can be extended to 0 or negative numbers

Arithmetic Expressions

Sum	+
Negation/Subtraction	-
Product	*
Division	/
Modulo	%
Power	٨

Relational Expressions

Equal to	==
Not equal to	~=
Less than	<
Greater than	>
Less than or equal to	<=
Greater than or equal to	>=

Logical Operators

not

and

or

Even though Lua does not have a Ternary operator (condition ? truevalue : falsevalue), we can use and and or to achieve a similar effect: value = (condition and truevalue)

In this case *and* returns truevalue when the condition is true and falsevalue otherwise

Tables

Tables are used with the table[key] syntax Example:

> t = {foo="bar"} -- Same as t={["foo"]="bar"}

> t.foo

bar

They can also be used as arrays

 $a = \{1, 2, 3\}$

But in this case, index starts at 1

 $a = \{[0]=1, [1]=2\}$

Tables can be extended to index 0 or even negative numbers

Table size can be found with:

 $> a = \{1, 2, 3\}$

> # a

3

Functions and modules

Functions

value = function(args) body end

function functionName(args) body end

Functions can be used as arguments:

function f(f2, arg1) f2(arg1) end

Return skips other code below it

Modules

A common module declaration usually is:

local mymodule = {}

function mymodule.foo() print("bar") end

return mymodule

As tables can have functions assigned to a key

To import it, just do:

> module = require("mymodule")

> module.foo()

bar

Also, you can make private functions by putting local in front of the function declaration.

Math Library

math.abs(number)

math.acos(radians), math.asin(radians), math.atan(radians)

math.ceil(number), math.floor(number)

Math Library (cont)

math.cos(radians), math.sin(radians), math.tan(radians)

math.deg(radians), math.rad(degrees)

math.exp(number), math.log(number)

math.min(num1, num2, ...), math.max(num1, num2, ...)

math.sqrt(number)

 $math.random(),\ math.random(upper),$

math.random(lower, upper)

math.randomseed(seed)

math.huge --represents infinity

math.pi

On trigonometric calculations, the number is expressed as radians.

On math.random() lower and upper are

math.huge can be also represented with - math.huge

Control Structures

if/else statement

if (condition1) then

block

elseif (condition2) then

block

else

block

end

while loop

while (condition) do

block

end

repeat loop

Like while loop, but condition is inverted

repeat

block

until (condition)

Numeric for loop

for variable = start, stop, step do

block

end

Iterator for loop

for var1, var2, var3 in iterator do

or falsevalue

Lua Scripting 5.1 Cheat Sheet

by SrGMC via cheatography.com/62984/cs/16090/

Control Structures (cont)

end

[, j]]])

Table Library

table.c Concatenate the elements of a table oncat(t- to form a string. Each element must able [, be able to be coerced into a string. sep [, i

table.fo Apply the function f to the elements of reach(t the table passed. On each iteration able, f) the function f is passed the key-value pair of that element in the table. Apply the function f to the elements of the table passed. On each iteration the function f is passed the key-value pair of that element in the table.

Deprecated

table.fo Apply the function f to the elements of reachi(the table passed. On each iteration table, the function f is passed the f) index-value pair of that element in the table. This is similar to table.foreach() except that index-value pairs are passed, not key-value pairs. Deprecated

Table Library (cont)

table.s Sort the elements of a table in-place.
ort(tabl- A comparison function can be
e [, provided to customise the element
comp]) sorting. The comparison function
must return a boolean value
specifying whether the first argument
should be before the second
argument in the sequence.

table.in Insert(ta poble, be [pos,] povalue)

Insert a given value into a table. If a position is given insert the value before the element currently at that position.

table.r emove-(table [, pos])

Remove an element from a table. If a position is specified the element at that the position is removed. The remaining elements are reindexed sequentially and the size of the table is updated to reflect the change. The element removed is returned by this function.

table.sort() example:

 $> t = \{ 3,2,5,1,4 \}$

> table.sort(t, function(a,b) return a < b end)

> = table.concat(t, ", ")

1, 2, 3, 4, 5

	String	
	string.byte(s [, i [, j]])	Return the numerical code the in through j-th character of the string passed.
	string.char(i 1, i2,)	Generate a string representing the character numerical code passed as arguments.
	string.find(s, pattern [, index [, plain]])	Find the first occurrence of the pattern in the string passed
	string.format (s, e1, e2,)	Create a formatted string from the format and arguments provided. This is similar to the printf("format",) function in C.
	string.gsub(Used simply it can replace all

s, pattern, replace [, n]) instances of the pattern provided with the replacement. A pair of values is returned, the modified string and the number of substitutions made. The optional fourth argument n can be used to limit the number of substitutions made

string.len(s) Return the length of the string passed.

string.lower(Make all the upper case s) characters lower case.

string.upper(Make all the lower case s) characters upper case.

Cheatography

Lua Scripting 5.1 Cheat Sheet

by SrGMC via cheatography.com/62984/cs/16090/

String (cont)

string.match Extract substrings by matching (s, pattern [, patterns. index])

string.rep(s, Generate a string which is n

n) copies of the string passed concatenated together.

string.revers Reverses a string. e(s)

string.sub(s, i [, j])

Return a substring of the string passed. The substring starts at i. If the third argument j is not given, the substring will end at the end of the string. If the third argument is given, the substring ends at and includes j.

All functions can be used directly in string by changing string. to s:, s being the string *Example*:

string.reverse("Test")
"Test":reverse()"

Classes. Table based

```
local Person = {}
Person.__index = Person
function Person.new(name, surname)
  local self = setmetatable({},
Person)
  self.name = name
  self.surname = surname
  return self
end
function Person.setName(self, name)
  self.name = name
end
function Person.getName(self)
  return self.name
end
function Person.setSurname(self, surname)
  self.surname = surname
end
function Person.getSurname(self)
```

Classes. Table based (cont)

```
return self.surname
end
return Person
-- Import with ClassName =
require("classname")
-- Use with local i =
ClassName.init(params)
```

Faster to create. Does not have private attributes

Classes. Closure/Instance Based

```
local function MyClass(init)
    local self = {
        public_field = 0
   local private_field = init
    function self.foo()
        return private_field
    function self.bar()
        private_field =
private_field + 1
   end
    return self
return MyClass
-- Import with MyClass =
require("MyClass")
-- Use with local i =
MyClass(init)
```

Can have private attributes. Slower to create
