

## Python basics Cheat Sheet

by stonekirby via cheatography.com/25026/cs/6414/

### **Primitive Datatypes and Operators**

```
# You have numbers
3 # => 3
# Math is what you would expect
1 + 1 # => 2
8 - 1 # => 7
10 * 2 # => 20
# Except division which returns floats, real numbers, by default
35 / 5 # => 7.0
# Result of integer division truncated down both for positive and negative.
5 // 3 # => 1
5.0 // 3.0 \# => 1.0 \# works on floats too
-5 // 3 # => -2
-5.0 // 3.0 # => -2.0
# When you use a float, results are floats
3 * 2.0 # => 6.0
# Modulo operation
7 % 3 # => 1
# Exponentiation (x**y, x to the yth power)
2**4 # => 16
# Enforce precedence with parentheses
(1 + 3) * 2 # => 8
# Boolean values are primitives (Note: the capitalization)
True
False
# negate with not
not True # => False
not False # => True
# Boolean Operators
# Note "and" and "or" are case-sensitive
True and False # => False
False or True # => True
# Note using Bool operators with ints
0 \text{ and } 2 \# => 0
-5 or 0 # => -5
0 == False # => True
2 == True # => False
1 == True # => True
# Equality is ==
1 == 1 # => True
2 == 1 # => False
# Inequality is !=
1 != 1 # => False
2 != 1 # => True
```

### Python basics Cheat Sheet

by stonekirby via cheatography.com/25026/cs/6414/

### **Primitive Datatypes and Operators (cont)**

# More comparisons

1 < 10 # => True

1 > 10 # => False

2 <= 2 # => True

2 >= 2 # => True

# Comparisons can be chained!

1 < 2 < 3 # => True

2 < 3 < 2 # => False

# (is vs. ==) is checks if two variable refer to the same object, but == checks

# if the objects pointed to have the same values.

a = [1, 2, 3, 4] # Point a at a new list, [1, 2, 3, 4]

b = a # Point b at what a is pointing to

b is a # => True, a and b refer to the same object

b == a # => True, a's and b's objects are equal

b = [1, 2, 3, 4] # Point a at a new list, [1, 2, 3, 4]

b is a # => False, a and b do not refer to the same object

b == a # => True, a's and b's objects are equal

### Using [None]

# None is an object

None # => None

# Don't use the equality "==" symbol to compare objects to None

# Use "is" instead. This checks for equality of object identity.

"etc" is None # => False

None is None # => True

# None, 0, and empty strings/lists/dicts all evaluate to False.

# All other values are True

bool(0) # => False

bool("") # => False

bool([]) # => False

bool({}) # => False

### **Strings**

# Strings are created with " or '

"This is a string."

'This is also a string.'

# Strings can be added too! But try not to do this.

"Hello " + "world!" # => "Hello world!"

# Strings can be added without using '+'

"Hello " "world!" # => "Hello world!"

# A string can be treated like a list of characters

"This is a string"[0] # = > T

# .format can be used to format strings, like this:

"{} can be {}".format("Strings", "interpolated") # => "Strings can be interpolated"

## Python basics Cheat Sheet by stonekirby via cheatography.com/25026/cs/6414/

### Strings (cont)

# You can repeat the formatting arguments to save some typing.

"{0} be nimble, {0} be quick, {0} jump over the {1}".format("Jack", "candle stick")

# => "Jack be nimble, Jack be quick, Jack jump over the candle stick"

# You can use keywords if you don't want to count.

"{name} wants to eat {food}".format(name="Bob", food="lasagna") # => "Bob wants to eat lasagna"

# If your Python 3 code also needs to run on Python 2.5 and below, you can also

# still use the old style of formatting:

"%s can be %s the %s way" % ("Strings", "interpolated", "old") # => "Strings can be interpolated the old way"

#### Lists

```
# Lists store sequences
li = []
# You can start with a prefilled list
other li = [4, 5, 6]
# Add stuff to the end of a list with append
li.append(1) # li is now [1]
li.append(2) # li is now [1, 2]
li.append(4) # li is now [1, 2, 4]
li.append(3) # li is now [1, 2, 4, 3]
# Remove from the end with pop
li.pop() # => 3 and li is now [1, 2, 4]
# Let's put it back
li.append(3) # li is now [1, 2, 4, 3] again.
# Access a list like you would any array
li[0] # => 1
# Look at the last element
li[-1] # => 3
# Looking out of bounds is an IndexError
li[4] # Raises an IndexError
# You can look at ranges with slice syntax.
# (It's a closed/open range for you mathy types.)
li[1:3] # => [2, 4]
# Omit the beginning
li[2:] # => [4, 3]
# Omit the end
li[:3] # => [1, 2, 4]
# Select every second entry
li[::2] # =>[1, 4]
# Return a reversed copy of the list
li[::-1] # => [3, 4, 2, 1]
# Use any combination of these to make advanced slices
# li[start:end:step]
# Make a one layer deep copy using slices
```

By **stonekirby** cheatography.com/stonekirby/

 $li2 = li[:] \# \Rightarrow li2 = [1, 2, 4, 3]$  but (li2 is li) will result in false.

# Python basics Cheat Sheet by stonekirby via cheatography.com/25026/cs/6414/

### Lists (cont)

# Remove arbitrary elements from a list with "del"

del li[2] # li is now [1, 2, 3]

# Remove first occurrence of a value

li.remove(2) # li is now [1, 3]

li.remove(2) # Raises a ValueError as 2 is not in the list

# Insert an element at a specific index

li.insert(1, 2) # li is now [1, 2, 3] again

# Get the index of the first item found matching the argument

li.index(2) # =>

li.index(4) # Raises a ValueError as 4 is not in the list

# You can add lists

# Note: values for li and for other li are not modified.

li + other\_li # => [1, 2, 3, 4, 5, 6]

# Concatenate lists with "extend()"

li.extend(other\_li) # Now li is [1, 2, 3, 4, 5, 6]

# Check for existence in a list with "in"

1 in li # => True

# Examine the length with "len()"

len(li) # => 6

### **Variables**

# Python has a print function

print("I'm Python. Nice to meet you!") # => I'm Python. Nice to meet you!

# By default the print function also prints out a newline at the end.

# Use the optional argument end to change the end character.

print("Hello, World", end="!") # => Hello, World!

# Simple way to get input data from console

 $input\_string\_var = input("Enter some \ data:") \ \# \ Returns \ the \ data \ as \ a \ string$ 

# Note: In earlier versions of Python, input() method was named as raw\_input()

# No need to declare variables before assigning to them.

# Convention is to use lower\_case\_with\_underscores

some\_var = 5

some\_var # => 5

# Accessing a previously unassigned variable is an exception.

# See Control Flow to learn more about exception handling.

some\_unknown\_var # Raises a NameError
